Adult Females in Nursery Areas				
Exposure to chlorpyrifos is sufficient to reduce female productivity via impairments to reproduction	High	High	Not Available	**Yes**
Juveniles in Nursery Areas				

Exposure to chlorpyrifos is sufficient to reduce juvenile abundance via acute lethality.	High	High	4-day: 33-84 **Error! Reference source not found.**	**Yes**
Exposure to chlorpyrifos is sufficient to reduce juvenile abundance via reduction in prey availability	High	High	4-day fish: 21-79 4-day invert: 44-97 **Error! Reference source not found.**	**Yes**
Exposure to chlorpyrifos is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	High	Not Available	**Yes**
Exposure to chlorpyrifos is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	**Yes**
Exposure to chlorpyrifos is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	High	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Smalltooth sawfish are anticipated to experience reduced abundance and productivity (adults) from exposure to chlorpyrifos. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where chlorpyrifos achieves predicted levels. The MagTool results indicate that between 33-84 percent of individuals within a population will die. Where formulated products and tank mixtures containing chlorpyrifos occur in aquatic habitats, sawfish will likely experience more toxicity. The overall risk to Smalltooth sawfish from the effects of the action is high and the confidence associated with that risk is high.

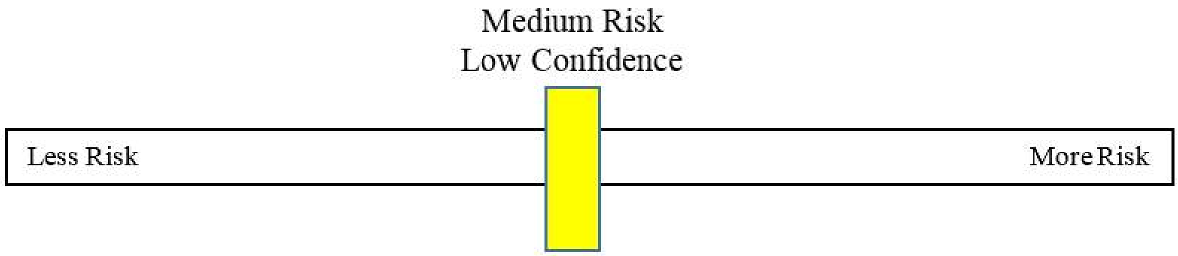
Risk Hypothesis				

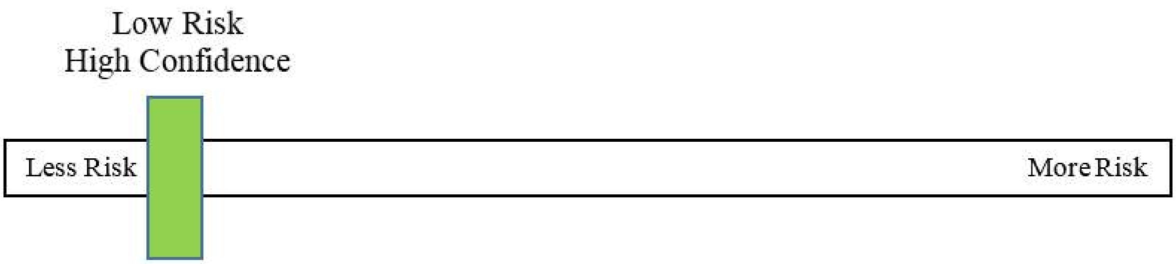
Exposure to chlorpyrifos is sufficient to reduce the abundance of larval/juvenile and adults via direct toxicity	High	Low	Not Available	**Yes**
Exposure to chlorpyrifos is sufficient to reduce the abundance of juvenile and adults via reduction in prey availability	High	Low	Not Available	**Yes**
Exposure to chlorpyrifos is sufficient to reduce the abundance and productivity of larval/juvenile and adults via impairments to ecologically significant behaviors (e.g. prey capture, settling, metamorphosis).	High	Low	Not Available	**Yes**
Exposure to chlorpyrifos is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	Low	Not Available	**Yes**
Exposure to chlorpyrifos is sufficient to reduce the abundance and productivity of larval/juvenile and adults via reductions in growth (direct toxicity)	High	Low	Not Available	**Yes**
Exposure to chlorpyrifos is sufficient to reduce the productivity of adults via impairments to reproduction.	High	Low	Not Available	Yes

Effects analysis summary: Adult, juvenile and larval black abalone are not anticipated to experience significant reductions in abundance and productivity (adults) from exposure to chlorpyrifos. Where formulated products and tank mixtures containing chlorpyrifos occur in aquatic habitats, abalone may experience increased toxicity. The overall risk to black abalone from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted chlorpyrifos concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the portion of the population which occupy tide-pools.



12.46 White Abalone (Haliotis sorenseni)

Effects analysis summary: Adult and juvenile white abalone are not anticipated to experience significant reductions in abundance and productivity (adults) from exposure to chlorpyrifos. The overall risk to white abalone from the effects of the action is low and the confidence associated with that risk is high. The low risk is due primarily to the proximity of white abalone habitat (marine off-shore; depths of 80-100 feet) relative to chlorpyrifos use sites.



12.47 Caribbean Corals (7 species): Orbicella franksi; Orbicella annularis; Orbicella faveolata; Mycetophyllia ferox; Acropora cervicornis; Acropora palmate; Dendrogyra cylindrus

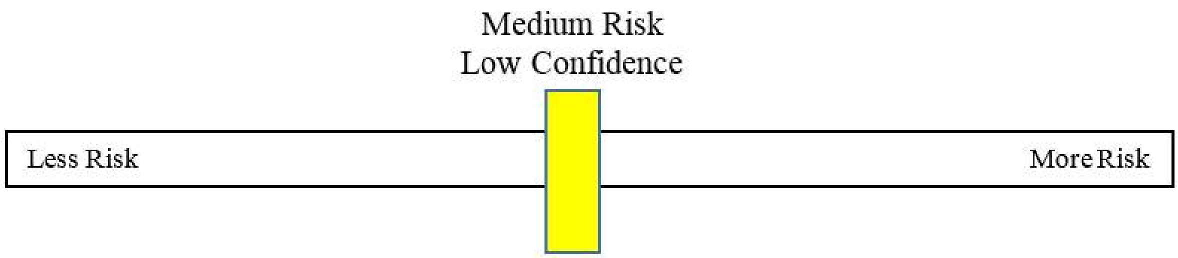
Effects analysis summary: Caribbean coral populations (7 species: Orbicella franksi; Orbicella annularis; Orbicella faveolata; Mycetophyllia ferox; Acropora cervicornis; Acropora palmate; Dendrogyra cylindrus) are not anticipated to experience significant reductions in abundance or productivity from exposure to chlorpyrifos. Where formulated products and tank mixtures containing chlorpyrifos occur in aquatic habitats, coral may experience increased toxicity. The overall risk to Caribbean corals (7 species) from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted chlorpyrifos concentrations in coastal habitats. Low confidence of risk is also attributed to the low portion of the species range within US territories.



12.48 Indo-Pacific Corals (7 species): Acropora retusa; Acropora globiceps; Seriatopora aculeate; Euphyllia paradivisa; Isopora crateriformis; Acropora jacquelineae; Acropora speciose

Exposure to chlorpyrifos is sufficient to reduce adult productivity via impairments to reproduction	Low	Low	Not Available	**No**
Exposure to chlorpyrifos is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	Low	Not Available	**No**

Effects analysis summary: Adult and juvenile Green sea turtle, central west pacific DPS are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to chlorpyrifos in the marine environment. If exposed to formulated products and tank mixtures containing chlorpyrifos, sea turtles may experience increased toxicity. The overall risk to Green sea turtle, central south pacific DPS from the effects of the action is low and the confidence associated with that risk is low. The low risk is due primarily to the small portion of the species range within US territories. The lack in confidence is due primarily to the uncertainty in predicted chlorpyrifos concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.

activity; the identified mechanism of toxicity				

Effects analysis summary: Adult and juvenile hawksbill sea turtles are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to chlorpyrifos in the marine environment. If exposed to formulated products and tank mixtures containing chlorpyrifos, sea turtles may experience increased toxicity. The overall risk to hawksbill sea turtles from the effects of the action is low and the confidence associated with that risk is low. The low risk is due primarily to the small portion of the species range within US territories. The lack in confidence is due primarily to the uncertainty in predicted chlorpyrifos concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.

Life Stage: Juveniles

Based on the life history of leatherback turtles, hatchlings crawl to the water and swim to offshore areas where they reside for several years. Therefore juveniles are not expected to experience substantial exposure to chlorpyrifos.

Life Stage: Adults

Effects analysis summary: Adult and juvenile leatherback sea turtles are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to chlorpyrifos in the marine environment. If exposed to formulated products and tank mixtures containing chlorpyrifos, sea turtles may experience increased toxicity. The overall risk to leatherback sea turtles from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted chlorpyrifos concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.

12.58 Loggerhead Sea Turtle, North Pacific Ocean DPS (Caretta caretta)

Effects analysis summary: Adult and juvenile loggerhead sea turtle, North Pacific Ocean DPS are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to chlorpyrifos in the marine environment. If exposed to formulated products and tank mixtures containing chlorpyrifos, sea turtles may experience increased toxicity. The overall risk to loggerhead sea turtle, North Pacific DPS from the effects of the action is low and the confidence associated with that risk is high. Low risk is due primarily to the small portion of the species range within US territories and the species utilization of off-shore habitats.

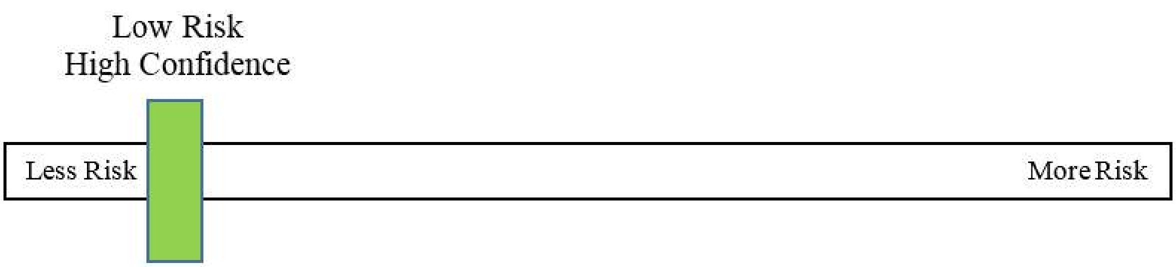
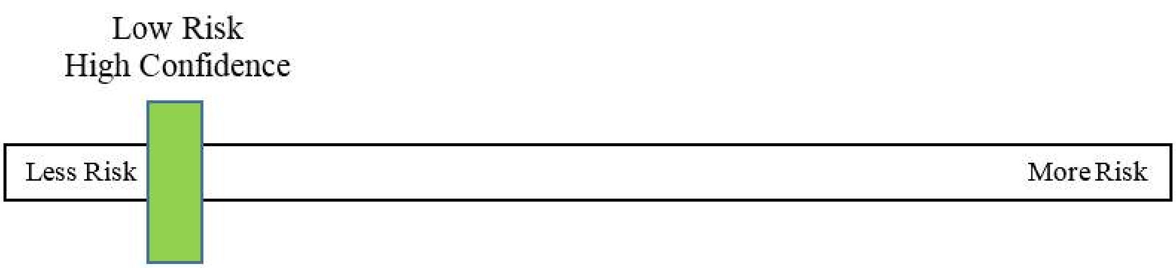
12.59 Olive Ridley Sea Turtle, Mexico's Pacific Coast Breeding Colonies (Lepidochelys olivacea)

Effects analysis summary: Adult and juvenile Olive ridley sea turtles within Mexico's Pacific breeding colonies are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to chlorpyrifos in the marine environment. If exposed to formulated products and tank mixtures containing chlorpyrifos, sea turtles may experience increased toxicity. The overall risk to Mexico's Pacific coast breeding colonies of Olive ridley sea turtles is low and the confidence associated with that risk is high. Low risk is due primarily to the small portion of the species range within US territories and the species' utilization of off-shore habitats.



12.60 Olive Ridley Sea Turtle, All Other Areas (Lepidochelys olivacea)

Effects analysis summary: Adult and juvenile Olive ridley sea turtles (all areas outside of Mexico's Pacific breeding colonies) are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to chlorpyrifos in the marine environment. If exposed to formulated products and tank mixtures containing chlorpyrifos, sea turtles may experience increased toxicity. The overall risk to Olive ridley sea turtles (all areas outside of Mexico's Pacific coast breeding colonies) is low and the confidence associated with that risk is high. Low risk is due primarily to the small portion of the species range within US territories and the species' utilization of off-shore habitats.



12.61 Killer Whale, Southern Resident DPS (Orcinus orca)

Risk Hypothesis: Exposure to chlorpyrifos is sufficient to reduce abundance via reduction in prey availability (primarily salmonids and other fish)		
Risk	**Confidence**	
High	**High**	

Effects analysis summary:

Adult and juvenile Killer whales (southern resident DPS) are anticipated to experience reduced abundance via reductions in prey from exposure to chlorpyrifos. The primary dietary item of the southern resident killer whale is salmon (predominantly Chinook). Chinook salmon populations have declined due to degradation of habitat, hydrology issues, harvest, and hatchery introgression; such reductions may require an increase in foraging effort. In addition, these prey contain environmental pollutants. These contaminants become concentrated at higher trophic levels and may lead to immune suppression or reproductive impairment. The overall risk to Killer whale, southern resident DPS from the effects of the action is high and the confidence associated with that risk is high.

The National Marine Fisheries Service (NMFS) qualitatively evaluated long-term effects on the Southern Residents from the anticipated appreciable reduction in the likelihood of survival and recovery of all 28 Pacific salmon Evolutionarily Significant Units (ESUs)/Distinct Population Segments (DPSs), and in particular, the nine Chinook salmon ESUs. We assessed the likelihood for localized depletions, and long-term implications for Southern Residents' survival and recovery, resulting from the increased risk of extinction of all listed Chinook salmon ESUs. In this way, NMFS can determine whether the increased likelihood of extinction of prey species is also likely to appreciably reduce the likelihood of survival and recovery of Southern Residents.

A reduction in prey would occur over time as abundance declined for the nine ESUs of Chinook salmon, along with the decline of lesser preferred prey ESUs/DPSs of other listed salmon. The continued depletion of these ESUs would also preclude the potential for their future recovery to healthy, more substantial numbers. Fewer populations contributing to Southern Residents' prey base will reduce the representation of diversity in life histories, resiliency in withstanding stochastic events, and redundancy to ensure there is a margin of safety for the salmon and Southern Residents to withstand catastrophic events.

The long-term reduction of the nine ESUs of Chinook salmon and other listed salmon and steelhead can lead to nutritional stress in the whales. Nutritional stress can lead to reduced body size and condition of individuals and can also lower reproductive and survival rates. Prey sharing would distribute more evenly the effects of prey limitation across individuals of the population that would otherwise be the case. Therefore, poor nutrition from the reduction of prey could contribute to additional mortality in this population. Food scarcity could also cause whales to draw on fat stores, mobilizing contaminants stored in their fat and affecting reproduction and immune function.

Differences in adult salmon life histories and locations of their natal streams likely affect the distribution of salmon across the Southern Residents' coastal range. The continued decline and potential extinction of the nine ESUs of Chinook salmon and other listed salmonids, and consequent interruption in the geographic continuity of salmon-bearing watersheds in the Southern Residents' coastal range, is likely to alter the distribution of migrating salmon and increase the likelihood of localized depletions in prey. This would have adverse effects on the Southern Residents' ability to meet their energy needs. A fundamental change in the prey base originating from the whales' geographic range is likely to result in Southern Residents abandoning areas in search of more abundant prey or expending substantial effort to find depleted prey resources. This potential increase in energy demands should have the same effect on an animal's energy budget as reductions in available energy, such as one would expect from reductions in prey.

exposure; the identified mechanism of toxicity				
Exposure to chlorpyrifos is sufficient to reduce adult productivity via impairments to reproduction via dietary exposure (fish)	High	Low	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Steller sea lion (western DPS) are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to chlorpyrifos in the marine environment. If exposed to formulated products and tank mixtures containing chlorpyrifos, sea lions may experience increased toxicity. The overall risk to Steller sea lion (western DPS) from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted chlorpyrifos concentrations in coastal habitats.

Exposure to chlorpyrifos is sufficient to reduce adult productivity via impairments to reproduction via dietary exposure (fish)	**Low**	**Medium**	Not Available	**No**

Effects analysis summary: Adult and juvenile Guadalupe fur seals are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to chlorpyrifos in the marine environment. If exposed to formulated products and tank mixtures containing chlorpyrifos, fur seals may experience increased toxicity. The overall risk to Guadalupe fur seals from the effects of the action is low and the confidence associated with that risk is medium. The Low risk is due primarily to the small portion of the species' range within US territories. The lack in confidence is due primarily to the uncertainty in predicted chlorpyrifos concentrations in coastal habitats.

Risk Hypothesis				
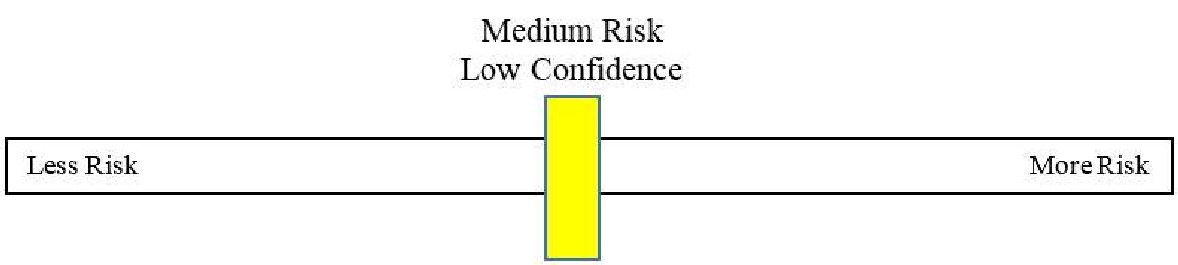
Exposure to the pesticide is sufficient to reduce abundance via direct mortality.	**NA**	**NA**	Not Available	**No**
Exposure to the pesticides is sufficient to reduce abundance via impacts to growth.	**High**	**Low**	Not Available	**Yes**

Effects analysis summary: Johnson's seagrass is not anticipated to experience significant reductions in abundance or productivity from exposure to chlorpyrifos in the marine environment. The overall risk to Johnson's seagrass from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted chlorpyrifos concentrations in coastal habitats.



CHAPTER 13

DIAZINON SPECIES EFFECTS ANALYSIS

TABLE OF CONTENTS

13 Diazinon Effects Analysis

13.1 Introduction

See Chapters 3 (Approach to the Assessment) and 11 (Effects Analysis Introduction) for descriptions of the methods and information used in this section. In this section we integrate the exposure and response information to evaluate the likelihood of adverse effects from stressors of the action at the population and species level. The information is organized by species. Within each species section the information is presented in the following order:

1. R- Plots figures: Demonstrate the relationship between geographically-specific exposure distributions and assessment measures (response distributions). These figures also convey the prevalence of registered use sites within the species range (example **Figure 1**).
2. Likelihood of exposure tables: Tables summarizing assessment of likelihood of exposure to each pesticide use that occurs within the species range (example **Table 1**).
3. Risk Hypotheses Tables: tables for each risk hypothesis summarizing risk and confidence associated with each registered use that occurs within the species range (example **Table 2**).
4. Final effects analysis table and narrative summary: Each species sections concludes with a Table indicating which risk hypotheses were supported and associated narrative summary of overall risk of the action to the species (example **Table 5**). Where applicable, the effects analysis table includes MagTool and/or Pacific salmon population model output. MagTool and population model output is also provided in appendix A: MagTool Results, and appendix B: Pacific Salmon Population Modeling.

13.2 Atlantic Salmon (Salmo salar)

Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	**High**	**Low**	**Not Available**	**Yes**

Effects analysis summary: Atlantic salmon are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to diazinon in the marine environment. If exposed to formulated products and tank mixtures containing diazinon, Atlantic salmon may experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed Atlantic salmon. The overall risk to Atlantic salmon from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted diazinon concentrations in coastal habitats. Low confidence of risk is also attributed to lack of information regarding duration of residency of Atlantic salmon in the coastal marine environment within US waters.

Risk Hypothesis					
Exposure to diazinon is sufficient to reduce juvenile and adult abundance via acute lethality.	Low	High	4-day: 0-1	Not Applicable	No
Exposure to diazinon is sufficient to reduce juvenile abundance via reduction in prey availability	Low	High	4-day fish: 0-1 4-day invert: 1-7		No
Exposure to diazinon is sufficient to reduce juvenile and adult abundance and adult productivity via impairments to ecologically significant behaviors	Low	High	Not Available	Not Applicable	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	High	Not Available		No
Exposure to diazinon is sufficient to reduce juvenile abundance via impacts to growth (direct toxicity)	Low	High	Not Available	Not Applicable	No

Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction	Low	High	Not Available	Not Applicable	No

Effects analysis summary: Adult and juvenile Columbia River ESU chum salmon are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to diazinon. The MagTool results indicate that between 0-1 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, chum may experience increased toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed chum. The overall risk to Columbia River ESU chum salmon from the effects of the action is low and the confidence associated with that risk is high.

Exposure to diazinon is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	Medium	Not Available	Not Applicable	Yes

Effects analysis summary: Adult and juvenile California Coastal Chinook salmon are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Population modelling results indicate that diazinon-induced mortality to juveniles may lead to severe reductions in lambda up to 86%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 0-1 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed Chinook. The overall risk to California Coastal Chinook salmon from the effects of the action is high and the confidence associated with that risk is medium. High risk is due to the proximity of orchards and vineyards use sites to the spawning streams of the Russian River population. Uses associated with the orchards and vineyards GIS layer are approved for use at times when individuals of this population are present. This population has been determined essential to the recovery of the ESU per the 2016 Coastal Multispecies Recovery Plan.

reduce ChE activity; the identified mechanism of toxicity				**Stream-Type Chinook:** 2-23% (3-5)	
Exposure to diazinon is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	Not Applicable	**Yes**

Effects analysis summary: Adult and juvenile Central Valley spring-run Chinook salmon are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Population modelling results indicate that diazinon-induced mortality to juveniles may lead to severe reductions in lambda up to 86%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 1-17 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed Chinook. The overall risk to Central Valley spring-run Chinook salmon from the effects of the action is high and the confidence associated with that risk is high.

Effects analysis summary: Adult and juvenile Chinook salmon, Lower Columbia River ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Population modelling results indicate that diazinon-induced mortality to juveniles may lead to severe reductions in lambda up to 86%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that 0 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed Chinook. The overall risk to Chinook salmon, Lower Columbia River ESU from the effects of the action is high and the confidence associated with that risk is high. High risk is due to the proximity of orchard and vineyard use sites to the White Salmon population's spawning streams and migratory corridor, as well as vegetable and ground fruit use sites in proximity to the migratory corridor near Sauvie Island, Oregon. Uses associated with the orchards and vineyards GIS layer are approved for use at times when individuals of the While Salmon population are present. This population has been determined essential to the recovery of the ESU per the 2013 Lower Columbia River Recovery Plan for Salmon and Steelhead.

	High	Medium	4-day:	**Ocean-Type Chinook**	Yes

Exposure to diazinon is sufficient to reduce juvenile abundance via acute lethality.			0-1	Portion of juveniles exposed to diazinon EECs; 100-2000 µg/l	Mean percent reduction (STD) in a population's intrinsic growth, lambda, from death of juveniles	
				25% 50% 75% 100%	0-12% (13-23) 1-23% (13-26) 1-35% (13-24) 1-86% (13-2)	
				Stream-Type Chinook		
				Portion of juveniles exposed to diazinon EECs; 100-2000 µg/l	Mean percent reduction (STD) in a population's intrinsic growth, lambda, from death of juveniles	
				25% 50% 75% 100%	0-11% (4-18) 0-20% (4-21) 1-31% (4-21) 1-84% (4-1)	
Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	Medium	Not Available	**Anticipated reductions in a population's intrinsic rate of growth (lambda) (± 1 STD)**		Yes
Exposure to diazinon is sufficient to reduce Juvenile abundance via reduction in prey availability	High	Medium	4-day invert: 1-6	**Ocean-Type Chinook:** 3-24% (8-10)		Yes
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	Medium	Not Available	**Stream-Type Chinook:** 2-23% (3-5)		Yes

Exposure to diazinon is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	Medium	Not Available	Not Applicable	**Yes**

Effects analysis summary: Adult and juvenile Chinook salmon, Puget Sound ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Population modelling results indicate that diazinon-induced mortality to juveniles may lead to severe reductions in lambda up to 86%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 0-1 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed Chinook. The overall risk to Chinook salmon, Puget Sound ESU from the effects of the action is high and the confidence associated with that risk is medium. High risk is due to the proximity of vegetables and ground fruit use sites to the Nooksack populations (middle fork, north fork, and south fork), the upper and lower Skagit populations, and the Sauk population. Uses associated with the vegetables and ground fruit GIS layer are approved for use at times when individuals of these populations are present. These populations have been determined essential to the recovery of the ESU per the 2007 Puget Sound Chinook Recovery Plan.

impairments to ecologically significant behaviors.					

Effects analysis summary: Adult and juvenile Chinook salmon, Snake River spring/summer-run ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Population modelling results indicate that diazinon-induced mortality to juveniles may lead to severe reductions in lambda up to 86%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 0-1 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed Chinook. The overall risk to Chinook salmon, Snake River spring/summer-run ESU from the effects of the action is high and the confidence associated with that risk is high. High risk is due, in part, to the proximity of orchards and vineyards use sites to the migratory corridor at the confluence of the Snake and Columbia rivers as well as at the confluence of the Yakima and Columbia rivers. All populations of this ESU utilize this migratory corridor.

Risk Hypothesis					
Exposure to diazinon is sufficient to reduce juvenile abundance via acute lethality.	High	High	4-day: 0-2	**Ocean-Type Chinook** Portion of juveniles exposed to diazinon EECs; 100-2000 µg/l / Mean percent reduction (STD) in a population's intrinsic growth, lambda, from death of juveniles 25% — 0-12% (13-23) 50% — 1-23% (13-26) 75% — 1-35% (13-24) 100% — 1-86% (13-2) **Stream-Type Chinook** Portion of juveniles exposed to diazinon EECs; 100-2000 µg/l / Mean percent reduction (STD) in a population's intrinsic growth, lambda, from death of juveniles 25% — 0-11% (4-18) 50% — 0-20% (4-21) 75% — 1-31% (4-21) 100% — 1-84% (4-1)	Yes
Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	High	Not Available	**Anticipated reductions in a population's intrinsic rate of growth (lambda) (± 1 STD)**	Yes
Exposure to diazinon is sufficient to	High	High	4-day invert: 4-29		Yes

reduce Juvenile abundance via reduction in prey availability				**Ocean-Type Chinook:** 3-24% (8-10)	
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	High	Not Available	**Stream-Type Chinook:** 2-23% (3-5)	Yes
Exposure to diazinon is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	Not Applicable	**Yes**

Effects analysis summary: Adult and juvenile Chinook salmon, upper Willamette River ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Population modelling results indicate that diazinon-induced mortality to juveniles may lead to severe reductions in lambda up to 86%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 0-4 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed Chinook. The overall risk to Chinook salmon, upper Willamette River ESU from the effects of the action is high and the confidence associated with that risk is high. High risk is due to the proximity of orchards and vineyards use sites to spawning streams of the Molalla, North Santiam, McKenzie, and middle-fork Willamette populations. Uses associated with the orchards and vineyards GIS layer are approved for use at times when individuals of these populations are present. These populations have been determined essential to the recovery of the ESU per the 2011 Upper Willamette River Conservation and Recovery Plan for Chinook Salmon and Steelhead.

Effects analysis summary: Adult and juvenile Coho salmon, lower Columbia River ESU are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to diazinon. Population modelling results indicate that diazinon-induced mortality to juveniles may lead to severe reductions in lambda up to 92%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that 0 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, Coho may experience increased toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed Coho. The overall risk to Coho salmon, lower Columbia River ESU from the effects of the action is low and the confidence associated with that risk is high. Low risk is attributed primarily to the lack of diazinon use sites proximal to the species habitat.

Exposure to diazinon is sufficient to reduce Juvenile abundance via reduction in prey availability	Low	High	4-day invert: 0	3-27% (7-8)	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	High	Not Available		No
Exposure to diazinon is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	Low	High	Not Available	Not Applicable	No

Effects analysis summary: Adult and juvenile Coho salmon, Oregon Coast ESU are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to diazinon. Population modelling results indicate that diazinon-induced mortality to juveniles may lead to severe reductions in lambda up to 92%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that 0 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, Coho may experience increased toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed Coho. The overall risk to Coho salmon, Oregon Coast ESU from the effects of the action is low and the confidence associated with that risk is high. Low risk is attributed primarily to the lack of diazinon use sites proximal to the species habitat.

Risk Hypothesis						
Exposure to diazinon is sufficient to reduce juvenile abundance via acute lethality.	Low	High	4-day: 0-3	Portion of juveniles exposed to diazinon EECs; 100-2000 µg/l	Mean percent reduction (STD) in a population's intrinsic growth, lambda, from death of juveniles	No
				25%	0-10% (8-19)	

				50% 1-19% (8-21) 75% 1-29% (8-21) 100% 1-83% (8-1)	
Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	Low	High	Not Available	**Anticipated reductions in a population's intrinsic rate of growth (lambda) (± 1 STD)**	No
Exposure to diazinon is sufficient to reduce Juvenile abundance via reduction in prey availability	Low	High	4-day invert: 3-18	2-23% (4-6)	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	High	Not Available		No
Exposure to diazinon is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	Low	High	Not Available	Not Applicable	No

Effects analysis summary: Adult and juvenile Sockeye salmon, Snake River ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Population modelling results indicate that diazinon-induced mortality to juveniles may lead to severe reductions in lambda up to 93%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 0-3 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, sockeye will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed sockeye. The overall risk to Sockeye salmon, Snake River ESU from the effects of the action is high and the confidence associated with that risk is medium.

Effects analysis summary: Adult and juvenile Steelhead, California Central Valley DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where diazinon achieves predicted levels. The MagTool results indicate that between 0-15 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed steelhead. The overall risk to Steelhead, California Central Valley DPS from the effects of the action is high and the confidence associated with that risk is high.

Exposure to diazinon is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Steelhead, Lower Columbia River DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where diazinon achieves predicted levels. The MagTool results indicate that 0 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed steelhead. The overall risk to Steelhead, Lower Columbia River DPS from the effects of the action is high and the confidence associated with that risk is high. High risk is due to the proximity of orchards and vineyards use sites to spawning streams of the Hood River winter-run population and vegetable and ground fruit use sites proximal to the migratory corridor at Sauvie Island. Uses associated with the orchards and vineyards GIS layer are approved for use at times when individuals of the Hood River winter-run population are present. This population has been determined essential to the recovery of the ESU per the 2011 Upper Willamette River Conservation and Recovery Plan for Chinook Salmon and Steelhead.

Risk Hypothesis				
Exposure to diazinon is sufficient to reduce juvenile abundance via acute lethality.	Low	High	4-day: 0-1	No
Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce Juvenile abundance via reduction in prey availability	Low	High	4-day fish: 0-1 4-day invert: 1-9	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	Low	High	Not Available	No

Effects analysis summary: Adult and juvenile Steelhead, Puget Sound DPS are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to diazinon. The MagTool results indicate that between 0-1 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, steelhead may experience increased toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed steelhead. The National Marine Fisheries Service (NMFS) was unable to assess whether or not use sites were proximal to sensitive areas because a recovery plan has not yet been generated and thus it is unclear which, if any, of the populations are considered essential to recovery. The overall risk to Steelhead, Puget Sound DPS from the effects of the action is low and the confidence associated with that risk is high. Low risk is attributed primarily to the lack of diazinon use sites proximal to the species habitat.

Effects analysis summary: Adult and juvenile Steelhead, South-Central California Coast DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where diazinon achieves predicted levels. The MagTool results indicate that between 0-3 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed steelhead. The overall risk to Steelhead, South-Central California Coast DPS from the effects of the action is high and the confidence associated with that risk is high. High risk is due, in part, to the proximity of vegetables and ground fruit use sites to spawning streams of the Salinas River watershed populations. Uses associated with the vegetables and ground fruit GIS layer are approved for use at times when individuals of these populations are present. All populations within the Salinas River watershed have been determined essential to the recovery of the ESU per the 2013 South-Central California Steelhead Recovery Plan.

Effects analysis summary: Adult and juvenile Steelhead, Southern California DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where diazinon achieves predicted levels. The MagTool results indicate that between 0-1 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed steelhead. The overall risk to Steelhead, Southern California DPS from the effects of the action is high and the confidence associated with that risk is high. High risk is due to the proximity of vegetables and ground fruit, and orchards and vineyards use sites to the spawning streams of the Monte Arido Highlands major population group. Uses associated with the vegetables and ground fruit, and orchards and vineyards GIS layers are approved for use at times when individuals of these populations are present. All populations within the Monte Arido Highlands major population group have been determined essential to the recovery of the ESU per the 2012 Southern California Steelhead Recovery Plan.

Effects analysis summary: Adult and juvenile Eulachon, Southern DPS are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to diazinon. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, eulachon may experience increased toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed eulachon. The overall risk to Eulachon, Southern DPS from the effects of the action is low and the confidence associated with that risk is high.

activity; the identified mechanism of toxicity				
Exposure to diazinon is sufficient to reduce juvenile abundance and productivity via impairments to ecologically significant behaviors.	High	High	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Green Sturgeon, Southern DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where diazinon achieves predicted levels. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, sturgeon will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed sturgeon. The overall risk to Green Sturgeon, Southern DPS from the effects of the action is high and the confidence associated with that risk is high. High risk is due primarily to the proximity of vegetables and ground fruit use sites to the mainstem of the Sacramento River.

Juveniles and Adults	**Risk**	**Confidence**	**Range in median percent mortalities for aquatic bins**	
Risk Hypothesis				
Exposure to diazinon is sufficient to reduce adult and juvenile abundance via acute lethality.	Low	High	4-day: 0	No
Exposure to diazinon is sufficient to reduce adult and juvenile abundance via reduction in prey availability	Low	High	4-day fish: 0 4-day invert: 0-5	No
Exposure to diazinon is sufficient to reduce adult and juvenile abundance and adult productivity via impairments to ecologically significant behaviors.	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	Low	High	Not Available	No

Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction	Low	High	Not Available	No

Effects analysis summary: Adult and juvenile Shortnose Sturgeon are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to diazinon. The MagTool results indicate that 0 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, sturgeon may experience increased toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed sturgeon in northern regions. The overall risk to Shortnose Sturgeon from the effects of the action is low and the confidence associated with that risk is high.

Risk Hypothesis				
Exposure to diazinon is sufficient to reduce adult and juvenile abundance via acute lethality.	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce adult and juvenile abundance via reduction in prey availability	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce adult and juvenile abundance and adult productivity via impairments to ecologically significant behaviors.	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	High	Not Available	No

Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction	Low	High	Not Available	No

Effects analysis summary: Adult and juvenile Atlantic sturgeon, Gulf of Maine DPS are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to diazinon. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, sturgeon may experience increased toxicity. The overall risk to Atlantic sturgeon, Gulf of Maine DPS from the effects of the action is low and the confidence associated with that risk is high.

Table 363. Effects analysis summary table: Atlantic sturgeon, New York Bight DPS and diazinon

	R-plot Derived	MagTool	

Juveniles and Adults	Risk	Confidence	Range in median percent mortalities for aquatic bins	Risk Hypothesis Supported? Yes/No
Risk Hypothesis				
Exposure to diazinon is sufficient to reduce adult and juvenile abundance via acute lethality.	High	High	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce adult and juvenile abundance via reduction in prey availability	High	High	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce adult and juvenile abundance and adult productivity via impairments to ecologically significant behaviors.	High	High	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	High	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	High	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction	High	High	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Atlantic sturgeon, New York Bight DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where diazinon achieves predicted levels. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, sturgeon will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of diazinon and mixtures containing Diazinon to exposed sturgeon. The overall risk to Atlantic sturgeon, New York Bight DPS from the effects of the action is high and the confidence associated with that risk is high. High risk is due primarily to vegetables and ground fruit use sites proximal to designated critical habitat along the mainstem of the Connecticut River, and orchards and vineyards use sites proximal to designated critical habitat along the mainstem of the Hudson River.

Exposure to diazinon is sufficient to reduce adult and	High	Medium	Not Available	**Yes**

juvenile abundance via acute lethality.				
Exposure to diazinon is sufficient to reduce adult and juvenile abundance via reduction in prey availability	High	Medium	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce adult and juvenile abundance and adult productivity via impairments to ecologically significant behaviors.	High	Medium	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	Medium	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	Medium	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction	High	Medium	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Atlantic Sturgeon, South Atlantic DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to diazinon. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where diazinon achieves predicted levels. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, sturgeon will likely experience more toxicity. The overall risk to Atlantic Sturgeon, South Atlantic DPS from the effects of the action is high and the confidence associated with that risk is medium. The high risk to the South Atlantic DPS is attributed primarily to high density areas of diazinon use (orchards and vineyards) proximal to sensitive areas within the species habitat. High risk is due primarily to the proximity of orchards and vineyards use sites to designated critical habitat along the South Fork Edisto River.

Table 379. Effects analysis summary table: Gulf Sturgeon and diazinon

	R-plot Derived		MagTool	Risk Hypothesis Supported? Yes/No
Juveniles and Adults	**Risk**	**Confidence**	**Range in median percent mortalities for aquatic bins**	
Risk Hypothesis				
Exposure to diazinon is sufficient to reduce adult and juvenile abundance via acute lethality.	Low	High	4-day: pending	No
Exposure to diazinon is sufficient to reduce adult and juvenile abundance via reduction in prey availability	Low	High	4-day fish: pending 4-day invert: pending	No
Exposure to diazinon is sufficient to reduce adult and juvenile abundance and adult productivity via impairments to ecologically significant behaviors.	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction	Low	High	Not Available	No

Effects analysis summary: Adult and juvenile Gulf Sturgeon are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to diazinon in the marine environment. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, sturgeon may experience increased toxicity. If exposed to formulated products and tank mixtures containing diazinon, Gulf sturgeon may experience increased toxicity. The MagTool results indicate that between [pending] percent of individuals within a population will die. The overall risk to Gulf Sturgeon from the effects of the action is low and the confidence associated with that risk is high.

Risk Hypothesis				
Exposure to diazinon is sufficient to reduce larval and juvenile abundance via acute lethality.	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce larval and juvenile abundance via impacts to growth (direct toxicity)	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce larval and juvenile abundance via reduction in prey availability	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce larval and juvenile abundance via impairments to ecologically significant behaviors.	Low	High	Not Available	No

Effects analysis summary: Adult, juvenile and larval Yelloweye Rockfish are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, rockfish may experience increased toxicity. If exposed to formulated products and tank mixtures containing diazinon, rockfish may experience increased toxicity. The overall risk to yelloweye rockfish from the effects of the action is low and the confidence associated with that risk is high. Low risk is attributed to uncertainty in the route of exposure to adult rockfish which are typically found in deep marine habitats. Low risk is also due to the minimal amount of diazinon use sites within the species range.

	R-plot Derived		**MagTool**	**Risk Hypothesis Supported? Yes/No**
Larvae and Juveniles	**Risk**	**Confidence**	**Range in median percent mortalities for aquatic bins**	
Risk Hypothesis				
Exposure to diazinon is sufficient to reduce larval and juvenile abundance via acute lethality.	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce larval and juvenile abundance via impacts to growth (direct toxicity)	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce larval and juvenile abundance via reduction in prey availability	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	High	Not Available	No
Exposure to diazinon is sufficient to reduce larval and juvenile abundance via impairments to ecologically significant behaviors.	Low	High	Not Available	No

Effects analysis summary: Adult, juvenile and larval boccacio are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, boccacio may experience increased toxicity. If exposed to formulated products and tank mixtures containing diazinon, boccacio may experience increased toxicity. The overall risk to boccacio from the effects of the action is low and the confidence associated with that risk is high. Low risk is attributed to uncertainty in the route of exposure to adult boccacio which are typically found in deep marine habitats. Low risk is also due to the minimal amount of diazinon use sites within the species range.

impairments to ecologically significant behaviors.				

Effects analysis summary: Adult and juvenile Gulf grouper are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, groupers may experience increased toxicity. The overall risk to Gulf grouper from the effects of the action is low and the confidence associated with that risk is high. The low risk to groupers is due primarily to the small portion of the species' range within US territories. Low risk is also attributed to uncertainty in the route of exposure to adult groupers which are typically found in deep marine habitats

Effects analysis summary: Adult and juvenile Nassau Grouper are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, groupers may experience increased toxicity. The overall risk to Nassau Grouper from the effects of the action is low and the confidence associated with that risk is high. The low risk to Nassau Grouper is due primarily to the small portion of the species' range within US territories. Low risk is also attributed to uncertainty in the route of exposure to adult groupers which are typically found in deep marine habitats.

Adults (Full Range)	**Risk**	**Confidence**	**Range in median percent mortalities for aquatic bins**	
Risk Hypothesis				
Exposure to diazinon is sufficient to reduce adult abundance via acute lethality.	**Low**	**High**	4-day: 0-1	No
Exposure to diazinon is sufficient to reduce adult abundance via reduction in prey availability	**Low**	**High**	4-day fish: 0-1 4-day invert: 1-7	No
Exposure to diazinon is sufficient to reduce ChE activity; mechanism of toxicity	**Low**	**High**	Not Available	No
Exposure to diazinon is sufficient to reduce adult abundance and productivity via impairments to ecologically significant behaviors.	**Low**	**High**	Not Available	No
Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction	**Low**	**High**	Not Available	No
Adult Females in Nursery Areas				
Exposure to diazinon is sufficient to reduce	**Low**	**High**	Not Available	**No**

female productivity via impairments to reproduction				
Juveniles in Nursery Areas				
Exposure to diazinon is sufficient to reduce juvenile abundance via acute lethality.	**Low**	**High**	4-day: 0-1	No
Exposure to diazinon is sufficient to reduce juvenile abundance via reduction in prey availability	**Low**	**High**	4-day fish: 0-1 4-day invert: 1-6	No
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	**Low**	**High**	Not Available	No
Exposure to diazinon is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	**Low**	**High**	Not Available	No
Exposure to diazinon is sufficient to reduce abundance via impacts to growth (direct toxicity)	**Low**	**High**	Not Available	No

Effects analysis summary: Adult and juvenile Smalltooth sawfish are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon. The MagTool results indicate that between 0-1 percent of individuals within a population will die. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, sawfish may experience increased toxicity. The overall risk to Smalltooth sawfish from the effects of the action is low and the confidence associated with that risk is high.

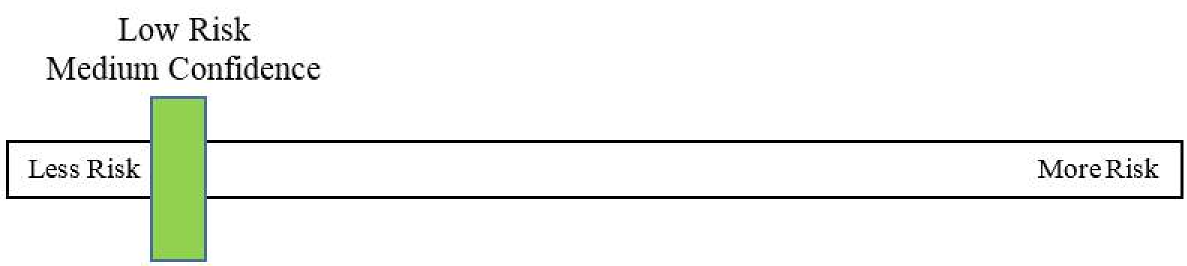
via reductions in growth (direct toxicity)				
Exposure to diazinon is sufficient to reduce the productivity of adults via impairments to reproduction.	Low	Medium	Not Available	No

Effects analysis summary: Adult, juvenile and larval black abalone are not anticipated to experience significant reductions in abundance and productivity (adults) from exposure to diazinon. Where formulated products and tank mixtures containing diazinon occur in aquatic habitats, abalone may experience increased toxicity. The overall risk to black abalone from the effects of the action is low and the confidence associated with that risk is medium. The lack in confidence is due primarily to the uncertainty in predicted diazinon concentrations in coastal habitats. Medium confidence of risk is also attributed to uncertainty regarding the portion of the population which occupy tide-pools.



13.46 White Abalone (Haliotis sorenseni)

Effects analysis summary: Adult and juvenile white abalone are not anticipated to experience significant reductions in abundance and productivity (adults) from exposure to diazinon. The overall risk to white abalone from the effects of the action is low and the confidence associated with that risk is high. The low risk is due primarily to the proximity of white abalone habitat (marine off-shore; depths of 80-100 feet) relative to diazinon use sites.

Risk Hypothesis				
Exposure to diazinon is sufficient to reduce adult abundance via acute lethality.	Medium	Low	Not Available	**No**
Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction	Medium	Low	Not Available	**No**
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	Low	Not Available	**No**

Effects analysis summary: Adult and juvenile Green sea turtle, central north pacific DPS are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. If exposed to formulated products and tank mixtures containing diazinon, sea turtles may experience increased toxicity. The overall risk to Green sea turtle, central north pacific DPS from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted diazinon concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites within the species range.

Effects analysis summary: Adult and juvenile hawksbill sea turtles are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. If exposed to formulated products and tank mixtures containing diazinon, sea turtles may experience increased toxicity. The overall risk to hawksbill sea turtles from the effects of the action is low and the confidence associated with that risk is low. The low risk is due primarily to the small portion of the species range within US territories. The lack in confidence is due primarily to the uncertainty in predicted diazinon concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.

Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction	Low	Low	Not Available	**No**
Exposure to diazinon is sufficient to reduce Juvenile abundance via reduction in prey availability	High	Low	Not Available	**Yes**
Exposure to diazinon is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	Low	Not Available	**NA**

Effects analysis summary: Adult and juvenile Kemp's ridley sea turtles are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. If exposed to formulated products and tank mixtures containing diazinon, sea turtles may experience increased toxicity. The overall risk to Kemp's ridley sea turtles from the effects of the action is low and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted diazinon concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.

Life Stage: Juveniles

Based on the life history of leatherback turtles, hatchlings crawl to the water and swim to offshore areas where they reside for several years. Therefore juveniles are not expected to experience substantial exposure to diazinon.

Life Stage: Adults

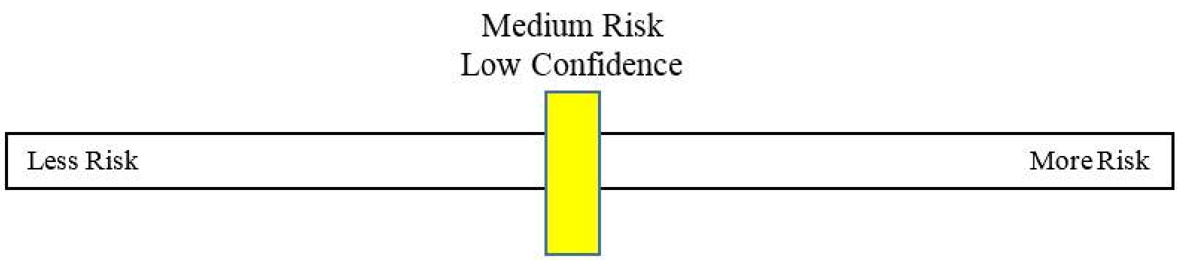
Effects analysis summary: Adult and juvenile leatherback sea turtles are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. If exposed to formulated products and tank mixtures containing diazinon, sea turtles may experience increased toxicity. The overall risk to leatherback sea turtles from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted diazinon concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.



13.58 Loggerhead Sea Turtle, North Pacific Ocean DPS (Caretta caretta)

Effects analysis summary: Adult and juvenile loggerhead sea turtle, North Pacific Ocean DPS are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. If exposed to formulated products and tank mixtures containing diazinon, sea turtles may experience increased toxicity. The overall risk to loggerhead sea turtle, North Pacific DPS from the effects of the action is low and the confidence associated with that risk is high. Low risk is due primarily to the small portion of the species range within US territories and the species utilization of off-shore habitats.

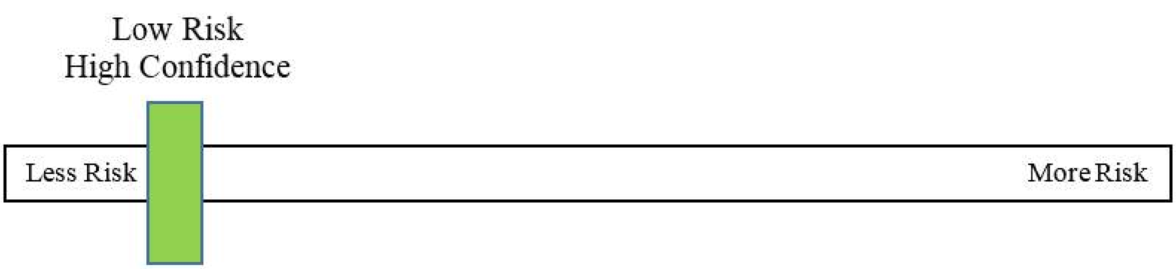
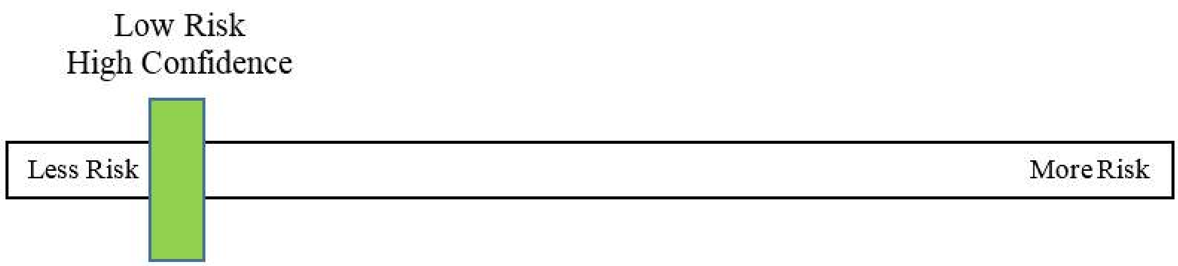
13.59 Olive Ridley Sea Turtle, Mexico's Pacific Coast Breeding Colonies (Lepidochelys olivacea)

Effects analysis summary: Adult and juvenile Olive ridley sea turtles within Mexico's Pacific breeding colonies are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. If exposed to formulated products and tank mixtures containing diazinon, sea turtles may experience increased toxicity. The overall risk to Mexico's Pacific coast breeding colonies of Olive ridley sea turtles is low and the confidence associated with that risk is high. Low risk is due primarily to the small portion of the species range within US territories and the species' utilization of off-shore habitats.



13.60 Olive Ridley Sea Turtle, All Other Areas (Lepidochelys olivacea)

Effects analysis summary: Adult and juvenile Olive ridley sea turtles (all areas outside of Mexico's Pacific breeding colonies) are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. If exposed to formulated products and tank mixtures containing diazinon, sea turtles may experience increased toxicity. The overall risk to Olive ridley sea turtles (all areas outside of Mexico's Pacific coast breeding colonies) is low and the confidence associated with that risk is high. Low risk is due primarily to the small portion of the species range within US territories and the species' utilization of off-shore habitats.



13.61 Killer Whale, Southern Resident DPS (Orcinus orca)

Risk Hypothesis: Exposure to diazinon is sufficient to reduce abundance via reduction in prey availability (primarily salmonids and other fish)		
Risk	**Confidence**	
High	**Medium**	

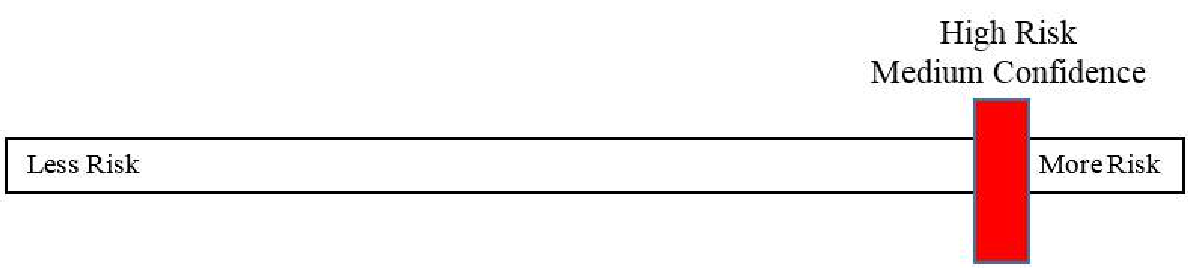
Effects analysis summary: Adult and juvenile Killer whales (southern resident DPS) are anticipated to experience reduced abundance via reductions in prey from exposure to diazinon. The primary dietary item of the southern resident killer whale is salmon (predominantly Chinook). Chinook salmon populations have declined due to degradation of habitat, hydrology issues, harvest, and hatchery introgression; such reductions may require an increase in foraging effort. In addition, these prey contain environmental pollutants. These contaminants become concentrated at higher trophic levels and may lead to immune suppression or reproductive impairment. The overall risk to Killer whale, southern resident DPS from the effects of the action is high and the confidence associated with that risk is medium.

NMFS qualitatively evaluated long-term effects on the Southern Residents from the anticipated appreciable reduction in the likelihood of survival and recovery of 20 Pacific salmon Evolutionarily Significant Units (ESUs)/District Population Segments (DPSs), and in particular, the nine Chinook salmon ESUs. We assessed the likelihood for localized depletions, and long-term implications for Southern Residents' survival and recovery, resulting from the increased risk of extinction of all listed Chinook salmon ESUs. In this way, NMFS can determine whether the increased likelihood of extinction of prey species is also likely to appreciably reduce the likelihood of survival and recovery of Southern Residents.

A reduction in prey would occur over time as abundance declined for the nine ESUs of Chinook salmon, along with the decline of lesser preferred prey ESUs/DPSs of other listed salmon. The continued depletion of these ESUs would also preclude the potential for their future recovery to healthy, more substantial numbers. Fewer populations contributing to Southern Residents' prey base will reduce the representation of diversity in life histories, resiliency in withstanding stochastic events, and redundancy to ensure there is a margin of safety for the salmon and Southern Residents to withstand catastrophic events.

The long-term reduction of the nine ESUs of Chinook salmon and other listed salmon and steelhead can lead to nutritional stress in the whales. Nutritional stress can lead to reduced body size and condition of individuals and can also lower reproductive and survival rates. Prey sharing would distribute more evenly the effects of prey limitation across individuals of the population that would otherwise be the case. Therefore, poor nutrition from the reduction of prey could contribute to additional mortality in this population. Food scarcity could also cause whales to draw on fat stores, mobilizing contaminants stored in their fat and affecting reproduction and immune function.

Differences in adult salmon life histories and locations of their natal streams likely affect the distribution of salmon across the Southern Residents' coastal range. The continued decline and potential extinction of the nine ESUs of Chinook salmon and other listed salmonids, and consequent interruption in the geographic continuity of salmon-bearing watersheds in the Southern Residents' coastal range, is likely to alter the distribution of migrating salmon and increase the likelihood of localized depletions in prey. This would have adverse effects on the Southern Residents' ability to meet their energy needs. A fundamental change in the prey base originating from the whales' geographic range is likely to result in Southern Residents abandoning areas in search of more abundant prey or expending substantial effort to find depleted prey resources. This potential increase in energy demands should have the same effect on an animal's energy budget as reductions in available energy, such as one would expect from reductions in prey.



13.62 Steller Sea Lion, Western DPS (Eumetopias jubatus)

Risk Hypothesis				

Exposure to diazinon is sufficient to reduce abundance via dietary aquatic exposure (inverts)	**Low**	**Medium**	Not Available	**No**
Exposure to diazinon is sufficient to reduce abundance via dietary aquatic exposure (fish)	**Low**	**Medium**	Not Available	**No**
Exposure to diazinon is sufficient to reduce abundance via reduction in prey availability (aquatic inverts)	**Low**	**Medium**	Not Available	**No**
Exposure to diazinon is sufficient to reduce abundance via reduction in prey availability (fish)	**Low**	**Medium**	Not Available	**No**
Exposure to diazinon is sufficient to reduce ChE activity via dietary exposure (inverts and fish); the identified mechanism of toxicity	**Low**	**Medium**	Not Available	**No**
Exposure to diazinon is sufficient to reduce adult productivity via impairments to reproduction via dietary exposure (fish)	**Low**	**Medium**	Not Available	**No**

Effects analysis summary: Adult and juvenile Guadalupe fur seals are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to diazinon in the marine environment. If exposed to formulated products and tank mixtures containing diazinon, fur seals may experience increased toxicity. The overall risk to Guadalupe fur seals from the effects of the action is low and the confidence associated with that risk is medium. The Low risk is due primarily to the small portion of the species' range within US territories. The lack in confidence is due primarily to the uncertainty in predicted diazinon concentrations in coastal habitats.

Risk Hypothesis				
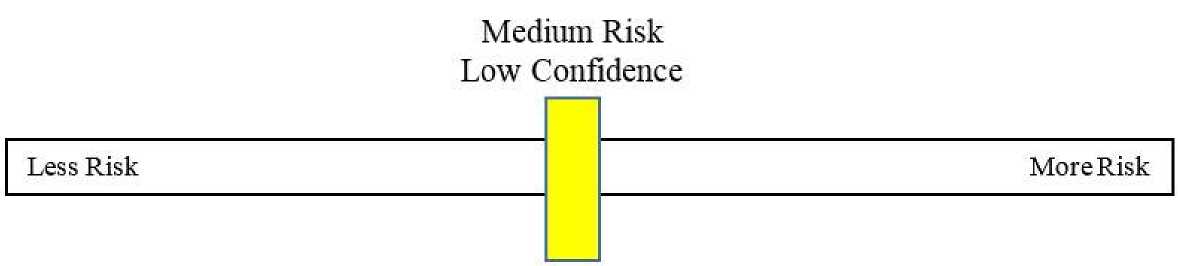
Exposure to the pesticide is sufficient to reduce abundance via direct mortality.	NA	NA	Not Available	No
Exposure to the pesticides is sufficient to reduce abundance via impacts to growth.	High	Low	Not Available	Yes

Effects analysis summary: Johnson's seagrass is not anticipated to experience significant reductions in abundance or productivity from exposure to diazinon in the marine environment. The overall risk to Johnson's seagrass from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted diazinon concentrations in coastal habitats.



CHAPTER 14

MALATHION SPECIES EFFECTS ANALYSIS

TABLE OF CONTENTS

14 MALATHION EFFECTS ANALYSIS

14.1 Introduction

See Chapters 3 (Approach to the Assessment) and 11 (Effects Analysis Introduction) for descriptions of the methods and information used in this section. In this section we integrate the exposure and response information to evaluate the likelihood of adverse effects from stressors of the action at the population and species level. The information is organized by species. Within each species section the information is presented in the following order:

1. R- Plots figures: Demonstrate the relationship between geographically-specific exposure distributions and assessment measures (response distributions). These figures also convey the prevalence of registered use sites within the species range (example **Figure 1**).
2. Likelihood of exposure tables: Tables summarizing assessment of likelihood of exposure to each pesticide use that occurs within the species range (example **Table 1**).
3. Risk Hypotheses Tables: tables for each risk hypothesis summarizing risk and confidence associated with each registered use that occurs within the species range (example **Table 2**).
4. Final effects analysis table and narrative summary: Each species sections concludes with a Table indicating which risk hypotheses were supported and associated narrative summary of overall risk of the action to the species (example **Table 5**). Where applicable, the effects analysis table includes MagTool and/or Pacific salmon population model output. MagTool and population model output is also provided in appendix A: MagTool Results, and appendix B: Pacific Salmon Population Modeling.

Risk Hypothesis: Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity		
Risk	**Confidence**	
High	**Low**	

Table 5. Effects analysis summary table: Atlantic salmon and malathion

	R-plot Derived		MagTool Range in median percent mortalities for aquatic bins	Risk Hypothesis Supported? Yes/No
Juveniles and Adults (Marine Environment Only)	**Risk**	**Confidence**		
Exposure to malathion is sufficient to reduce adult and juvenile abundance via acute lethality.	**High**	**Low**	**Not Available**	**Yes**
Exposure to malathion is sufficient to reduce adult and juvenile abundance and adult productivity via impairments to ecologically significant behaviors.	**High**	**Low**	**Not Available**	**Yes**
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	**High**	**Low**	**Not Available**	**Yes**

Effects analysis summary: Atlantic salmon are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, Atlantic salmon may experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed Atlantic salmon. The overall risk to Atlantic salmon from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats. Low confidence of risk is also attributed to lack of information regarding duration of residency of Atlantic salmon in the coastal marine environment within US waters.

Life Stage: Adults	**Risk**	**Confidence**	**Range in median percent mortalities for aquatic bins**	**Population Model Results**	**Hypothesis Supported? Yes/No**
Risk Hypothesis					
Exposure to malathion is sufficient to reduce juvenile and adult abundance via acute lethality.	High	High	4-day: 1-15	Not Applicable	Yes
Exposure to malathion is sufficient to reduce juvenile abundance via reduction in prey availability	High	High	4-day invert: 16-45	Not Applicable	Yes
Exposure to malathion is sufficient to reduce juvenile and adult abundance and adult productivity via impairments to ecologically significant behaviors	High	High	Not Available		Yes
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	High	Not Available		Yes
Exposure to malathion is sufficient to reduce juvenile abundance via impacts to growth (direct toxicity)	Medium	High	Not Available	Not Applicable	Yes
Exposure to malathion is sufficient to reduce adult productivity via impairments to reproduction	High	High	Not Available	Not Applicable	Yes

Effects analysis summary: Adult and juvenile Columbia River ESU chum salmon are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 1-15 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, chum will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed chum. The overall risk to Columbia River ESU chum salmon from the effects of the action is high and the confidence associated with that risk is high.

Exposure to malathion is sufficient to reduce adult productivity via impairments to reproduction	**High**	**Medium**	Not Available	Not Applicable	Yes

Effects analysis summary: Adult and juvenile Hood Canal summer-run ESU chum salmon are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 1-5 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, chum will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed chum. The overall risk to Hood Canal summer-run ESU chum from the effects of the action is high and the confidence associated with that risk is high.

Effects analysis summary: Adult and juvenile California Coastal Chinook salmon are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Population modelling results indicate that malathion-induced mortality to juveniles may lead to severe reductions in lambda up to 97%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 1-11 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed Chinook. The overall risk to California Coastal Chinook salmon from the effects of the action is high and the confidence associated with that risk is high.

Effects analysis summary: Adult and juvenile Central Valley spring-run Chinook salmon are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Population modelling results indicate that malathion-induced mortality to juveniles may lead to severe reductions in lambda up to 97%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 17-65 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed Chinook. The overall risk to Central Valley spring-run Chinook salmon from the effects of the action is high and the confidence associated with that risk is high.

Exposure to malathion is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	Not Applicable	**Yes**

Effects analysis summary: Adult and juvenile Chinook salmon, Puget Sound ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Population modelling results indicate that malathion-induced mortality to juveniles may lead to severe reductions in lambda up to 97%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 1-11 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed Chinook. The overall risk to Chinook salmon, Puget Sound ESU from the effects of the action is high and the confidence associated with that risk is high.

Exposure to malathion is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	Not Applicable	**Yes**

Effects analysis summary: Adult and juvenile Chinook salmon, Snake River fall-run ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Population modelling results indicate that malathion-induced mortality to juveniles may lead to severe reductions in lambda up to 97%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 0-35 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed Chinook. The overall risk to Chinook salmon, Snake River fall-run ESU from the effects of the action is high and the confidence associated with that risk is high.

Exposure to malathion is sufficient to reduce juvenile abundance via acute lethality.	High	High	4-day: 0-19	**Ocean-Type Chinook** Portion of juveniles exposed to malathion EECs; 10-1000 µg/l — Mean percent reduction (STD) in a population's intrinsic growth, lambda, from death of juveniles 25% — 1-12% (13-23) 50% — 1-23% (13-26) 75% — 2-35% (13-24) 100% — 3-97% (13-0) **Stream-Type Chinook** Portion of juveniles exposed to malathion EECs; 10-1000 µg/l — Mean percent reduction (STD) in a population's intrinsic growth, lambda, from death of juveniles 25% — 1-11% (5-18) 50% — 1-21% (5-22) 75% — 2-31% (4-21) 100% — 2-96% (4-0)	Yes

Exposure to malathion is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	High	Not Available	**Anticipated reductions in a population's intrinsic rate of growth (lambda) (± 1 STD)**	Yes
Exposure to malathion is sufficient to reduce Juvenile abundance via reduction in prey availability	High	High	4-day invert: 20-49	**Ocean-Type Chinook:** 3-25% (8-10) **Stream-Type Chinook:** 2-24% (3-5)	Yes
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	High	Not Available		Yes
Exposure to malathion is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	Not Applicable	**Yes**

Effects analysis summary: Adult and juvenile Chinook salmon, upper Columbia spring-run ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Population modelling results indicate that malathion-induced mortality to juveniles may lead to severe reductions in lambda up to 97%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 0-19 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, Chinook will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed Chinook. The overall risk to Chinook salmon, upper Columbia spring-run ESU from the effects of the action is high and the confidence associated with that risk is high.

Effects analysis summary: Adult and juvenile Coho salmon, Oregon coast ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Population modelling results indicate that malathion-induced mortality to juveniles may lead to severe reductions in lambda up to 99%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 0-9 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, Coho will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed Coho. The overall risk to Coho salmon, Oregon coast ESU from the effects of the action is high and the confidence associated with that risk is high.

Exposure to malathion is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	Not Applicable	**Yes**

Effects analysis summary: Adult and juvenile Coho salmon, southern Oregon/northern California coast ESU are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Population modelling results indicate that malathion-induced mortality to juveniles may lead to severe reductions in lambda up to 99%. Also, lambda may also be reduced due to reductions in juvenile growth via reduced prey abundance, cholinesterase activity, and impaired swimming. The MagTool results indicate that between 1-7 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, Coho will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed Coho. The overall risk to Coho salmon, southern

Oregon/northern California coast ESU from the effects of the action is high and the confidence associated with that risk is high.

Effects analysis summary: Adult and juvenile Steelhead, California Central Valley DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 16-61 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed steelhead. The overall risk to Steelhead, California Central Valley DPS from the effects of the action is high and the confidence associated with that risk is high.

Effects analysis summary: Adult and juvenile Steelhead, Lower Columbia River DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 0-9 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed steelhead. The overall risk to Steelhead, Lower Columbia River DPS from the effects of the action is high and the confidence associated with that risk is high.

Exposure to malathion is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce Juvenile abundance via reduction in prey availability	High	High	4-day fish: 0-8 4-day invert: 8-47	**Yes**

Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Steelhead, Northern California DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 1-8 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed steelhead. The overall risk to Steelhead, Northern California DPS from the effects of the action is high and the confidence associated with that risk is high.

Exposure to malathion is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Steelhead, Snake River Basin DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 0-21 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed steelhead. The overall risk to Steelhead, Snake River Basin DPS from the effects of the action is high and the confidence associated with that risk is high.

Effects analysis summary: Adult and juvenile Steelhead, Southern California DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 3-15 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed steelhead. The overall risk to Steelhead, Southern California DPS from the effects of the action is high and the confidence associated with that risk is high.

Effects analysis summary: Adult and juvenile Steelhead, Upper Columbia River DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 0-19 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, steelhead will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed steelhead. The overall risk to Steelhead, Upper Columbia River DPS from the effects of the action is high and the confidence associated with that risk is high.

Risk Hypothesis				
Exposure to malathion is sufficient to reduce juvenile and adult abundance via acute lethality.	High	High	Not Available	Yes
Exposure to malathion is sufficient to reduce juvenile abundance via reduction in prey availability	High	High	Not Available	Yes
Exposure to malathion is sufficient to reduce juvenile and adult abundance and adult productivity via impairments to ecologically significant behaviors	High	Medium	Not Available	Yes
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	Medium	Not Available	Yes
Exposure to malathion is sufficient to reduce juvenile abundance via impacts to growth (direct toxicity)	High	Medium	Not Available	Yes
Exposure to malathion is sufficient to reduce adult productivity via impairments to reproduction	High	Medium	Not Available	Yes

Effects analysis summary: Adult and juvenile Eulachon, Southern DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, eulachon will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed eulachon. The overall risk to Eulachon, Southern DPS from the effects of the action is high and the confidence associated with that risk is high.

	R-plot Derived		**MagTool**	**Risk Hypothesis Supported? Yes/No**
Juveniles and Adults	**Risk**	**Confidence**	**Range in median percent mortalities for aquatic bins**	
Risk Hypothesis				
Exposure to malathion is sufficient to reduce adult and juvenile abundance via acute lethality.	High	High	4-day: 0-8	**Yes**
Exposure to malathion is sufficient to reduce adult and juvenile abundance via reduction in prey availability	High	High	4-day fish: 0-8 4-day invert: 0-38	**Yes**
Exposure to malathion is sufficient to reduce adult and juvenile abundance and adult productivity via impairments to ecologically significant behaviors.	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce adult productivity via impairments to reproduction	High	High	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Shortnose Sturgeon are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 0-8 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, sturgeon will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed sturgeon in northern regions. The overall risk to Shortnose Sturgeon from the effects of the action is high and the confidence associated with that risk is high.

	R-plot Derived	**MagTool**	

Juveniles and Adults	Risk	Confidence	Range in median percent mortalities for aquatic bins	Risk Hypothesis Supported? Yes/No
Risk Hypothesis				
Exposure to malathion is sufficient to reduce adult and juvenile abundance via acute lethality.	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce adult and juvenile abundance via reduction in prey availability	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce adult and juvenile abundance and adult productivity via impairments to ecologically significant behaviors.	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce adult productivity via impairments to reproduction	High	High	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Atlantic sturgeon, Gulf of Maine DPS are anticipated to experience reduced abundance and productivity (spawning adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, sturgeon will likely experience more toxicity. Elevated water temperatures are anticipated to further enhance the toxicity of malathion and mixtures containing Malathion to exposed sturgeon. The overall risk to Atlantic sturgeon, Gulf of Maine DPS from the effects of the action is high and the confidence associated with that risk is high.

Juveniles and Adults	Risk	Confidence	Range in median percent mortalities for aquatic bins	Risk Hypothesis Supported? Yes/No
Risk Hypothesis				
Exposure to malathion is sufficient to reduce adult and juvenile abundance via acute lethality.	High	Low	4-day:	**Yes**
Exposure to malathion is sufficient to reduce adult and juvenile abundance via reduction in prey availability	High	Low	4-day fish: 4-day invert:	**Yes**
Exposure to malathion is sufficient to reduce adult and juvenile abundance and adult productivity via impairments to ecologically significant behaviors.	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce adult productivity via impairments to reproduction	High	Low	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Gulf Sturgeon are not anticipated to experience significant reductions in abundance or productivity (spawning adults) from exposure to malathion in the marine environment. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, sturgeon may experience increased toxicity. If exposed to formulated products and tank mixtures containing malathion, Gulf sturgeon may experience increased toxicity. The MagTool results indicate that between 20-69 percent of individuals within a population will die. The overall risk to Gulf Sturgeon from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats.

activity; the identified mechanism of toxicity				
Exposure to malathion is sufficient to reduce larval and juvenile abundance via impairments to ecologically significant behaviors.	High	Low	Not Available	**Yes**

Effects analysis summary: Adult, juvenile and larval Yelloweye Rockfish are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, rockfish may experience increased toxicity. If exposed to formulated products and tank mixtures containing malathion, rockfish may experience increased toxicity. The overall risk to yelloweye rockfish from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty in the route of exposure to adult rockfish which are typically found in deep marine habitats.

Risk Hypothesis				
Exposure to malathion is sufficient to reduce larval and juvenile abundance via acute lethality.	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce larval and juvenile abundance via impacts to growth (direct toxicity)	High	Low	Not Available	**Yes**

Exposure to malathion is sufficient to reduce larval and juvenile abundance via reduction in prey availability	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce larval and juvenile abundance via impairments to ecologically significant behaviors.	High	Low	Not Available	**Yes**

Effects analysis summary: Adult, juvenile and larval boccacio are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, boccacio may experience increased toxicity. If exposed to formulated products and tank mixtures containing malathion, boccacio may experience increased toxicity. The overall risk to boccacio from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty in the route of exposure to adult boccacio which are typically found in deep marine habitats.

Exposure to malathion is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	Low	**High**	Not Available	**No**

Effects analysis summary: Adult and juvenile Gulf grouper are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, groupers may experience increased toxicity. The overall risk to Gulf grouper from the effects of the action is low and the confidence associated with that risk is high. The low risk to groupers is due primarily to the small portion of the species' range within US territories. Low risk is also attributed to uncertainty in the route of exposure to adult groupers which are typically found in deep marine habitats

Exposure to malathion is sufficient to reduce juvenile abundance via reduction in prey availability	**Low**	**High**	Not Available	**No**

Effects analysis summary: Adult and juvenile Nassau Grouper are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, groupers may experience increased toxicity. The overall risk to Nassau Grouper from the effects of the action is low and the confidence associated with that risk is high. The low risk to Nassau Grouper is due primarily to the small portion of the species' range within US territories. Low risk is also attributed to uncertainty in the route of exposure to adult groupers which are typically found in deep marine habitats.

juvenile abundance via acute lethality.				
Exposure to malathion is sufficient to reduce juvenile abundance via reduction in prey availability	High	High	4-day fish: 0-3 4-day invert: 3-14	**Yes**
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce juvenile abundance via impairments to ecologically significant behaviors.	High	High	Not Available	**Yes**
Exposure to malathion is sufficient to reduce abundance via impacts to growth (direct toxicity)	High	High	Not Available	**Yes**

Effects analysis summary: Adult and juvenile Smalltooth sawfish are anticipated to experience reduced abundance and productivity (adults) from exposure to malathion. Reduced cholinesterase activity, reduced productivity, reduced prey abundance, and impaired behaviors including ability to swim are anticipated to occur in areas where malathion achieves predicted levels. The MagTool results indicate that between 0-4 percent of individuals within a population will die. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, sawfish will likely experience more toxicity. The overall risk to Smalltooth sawfish from the effects of the action is high and the confidence associated with that risk is high.

Risk Hypothesis				

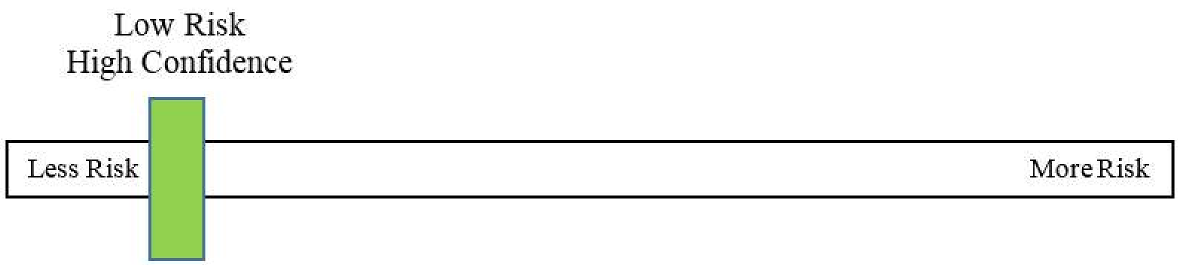
Exposure to malathion is sufficient to reduce the abundance of larval/juvenile and adults via direct toxicity	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce the abundance of juvenile and adults via reduction in prey availability	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce the abundance and productivity of larval/juvenile and adults via impairments to ecologically significant behaviors (e.g. prey capture, settling, metamorphosis).	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce the abundance and productivity of larval/juvenile and adults via reductions in growth (direct toxicity)	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce the productivity of adults via impairments to reproduction.	High	Low	Not Available	Yes

Effects analysis summary: Adult, juvenile and larval black abalone are not anticipated to experience significant reductions in abundance and productivity (adults) from exposure to malathion. Where formulated products and tank mixtures containing malathion occur in aquatic habitats, abalone may experience increased toxicity. The overall risk to black abalone from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the portion of the population which occupy tide-pools.

Medium Risk
Low Confidence
Less Risk
More Risk

14.46 White Abalone (Haliotis sorenseni)

Effects analysis summary: Adult and juvenile white abalone are not anticipated to experience significant reductions in abundance and productivity (adults) from exposure to malathion. The overall risk to white abalone from the effects of the action is low and the confidence associated with that risk is high. The low risk is due primarily to the proximity of white abalone habitat (marine off-shore; depths of 80-100 feet) relative to malathion use sites.



14.47 Caribbean Corals (7 species): Orbicella franksi; Orbicella annularis; Orbicella faveolata; Mycetophyllia ferox; Acropora cervicornis; Acropora palmate; Dendrogyra cylindrus

Risk Hypothesis				
Exposure to malathion is sufficient to reduce adult abundance via acute lethality.	Low	Low	Not Available	**No**
Exposure to malathion is sufficient to reduce adult productivity via impairments to reproduction	Low	Low	Not Available	**No**
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	Low	Not Available	**No**

Effects analysis summary: Adult and juvenile Green sea turtle, central north pacific DPS are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, sea turtles may experience increased toxicity. The overall risk to Green sea turtle, central north pacific DPS from the effects of the action is low and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites within the species range.

Adults	Risk	Confidence	Range in median percent mortalities for aquatic bins	Risk Hypothesis Supported? Yes/No
Risk Hypothesis				
Exposure to malathion is sufficient to reduce adult abundance via acute lethality.	Low	Low	Not Available	**No**
Exposure to malathion is sufficient to reduce adult productivity via impairments to reproduction	Low	Low	Not Available	**No**
Exposure to malathion is sufficient to reduce ChE activity; the identified mechanism of toxicity	Low	Low	Not Available	**No**

Effects analysis summary: Adult and juvenile Green sea turtle, central south pacific DPS are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, sea turtles may experience increased toxicity. The overall risk to Green sea turtle, central south pacific DPS from the effects of the action is low and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.

Effects analysis summary: Adult and juvenile hawksbill sea turtles are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, sea turtles may experience increased toxicity. The overall risk to hawksbill sea turtles from the effects of the action is low and the confidence associated with that risk is low. The low risk is due primarily to the small portion of the species range within US territories. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.

Life Stage: Juveniles

Based on the life history of leatherback turtles, hatchlings crawl to the water and swim to offshore areas where they reside for several years. Therefore juveniles are not expected to experience substantial exposure to malathion.

Life Stage: Adults

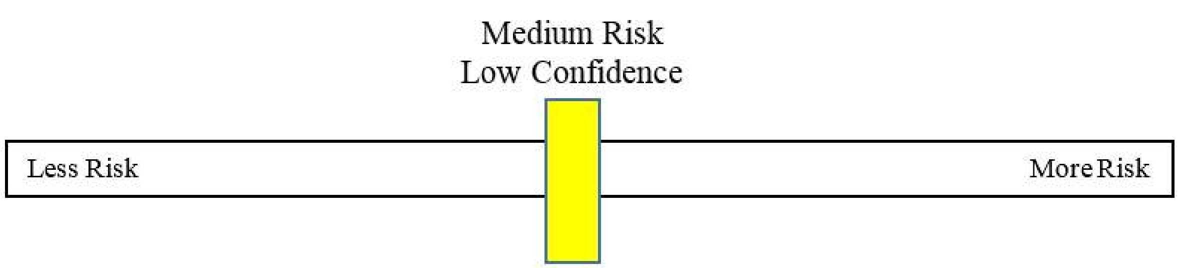
Effects analysis summary: Adult and juvenile leatherback sea turtles are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, sea turtles may experience increased toxicity. The overall risk to leatherback sea turtles from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.



14.58 Loggerhead Sea Turtle, North Pacific Ocean DPS (Caretta caretta)

Effects analysis summary: Adult and juvenile loggerhead sea turtle, North Pacific Ocean DPS are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, sea turtles may experience increased toxicity. The overall risk to loggerhead sea turtle, North Pacific DPS from the effects of the action is low and the confidence associated with that risk is high. Low risk is due primarily to the small portion of the species range within US territories and the species utilization of off-shore habitats.

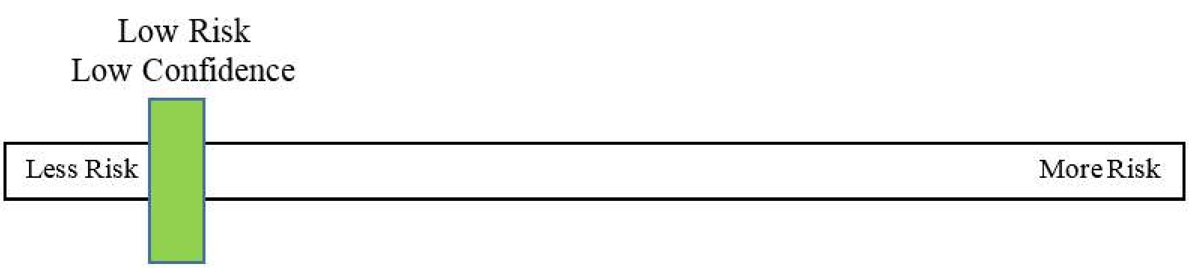
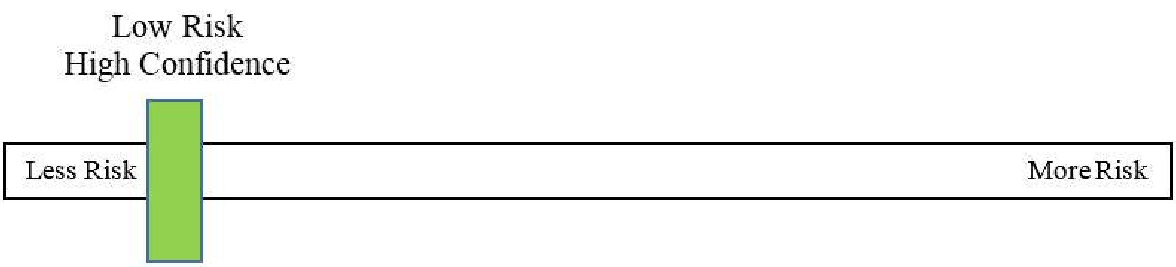
Juvenile abundance via reduction in prey availability				

Effects analysis summary: Adult and juvenile loggerhead sea turtles, northwest Atlantic Ocean DPS are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, sea turtles may experience increased toxicity. The overall risk to loggerhead sea turtles from the effects of the action is low and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats. Low confidence of risk is also attributed to uncertainty regarding the location of pesticide use sites with the species range.



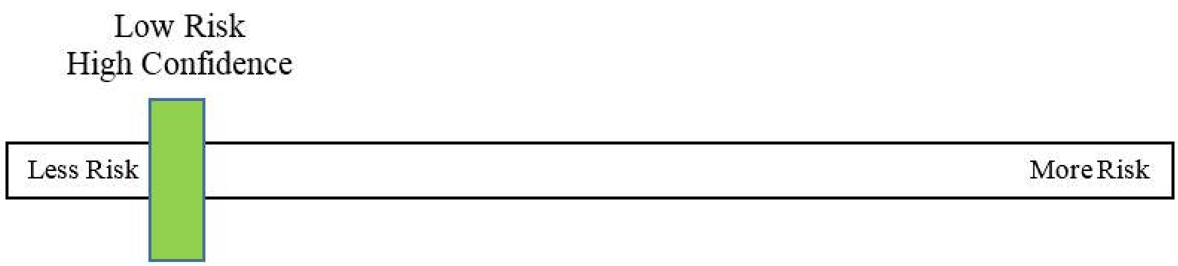
Olive Ridley Sea Turtle, Mexico's Pacific Coast Breeding Colonies (Lepidochelys olivacea)

Effects analysis summary: Adult and juvenile Olive ridley sea turtles within Mexico's Pacific breeding colonies are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, sea turtles may experience increased toxicity. The overall risk to Mexico's Pacific coast breeding colonies of Olive ridley sea turtles is low and the confidence associated with that risk is high. Low risk is due primarily to the small portion of the species range within US territories and the species' utilization of off-shore habitats.



14.60 Olive Ridley Sea Turtle, All Other Areas (Lepidochelys olivacea)

Effects analysis summary: Adult and juvenile Olive ridley sea turtles (all areas outside of Mexico's Pacific breeding colonies) are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, sea turtles may experience increased toxicity. The overall risk to Olive ridley sea turtles (all areas outside of Mexico's Pacific coast breeding colonies) is low and the confidence associated with that risk is high. Low risk is due primarily to the small portion of the species range within US territories and the species' utilization of off-shore habitats.



14.61 Killer Whale, Southern Resident DPS (Orcinus orca)

Risk Hypothesis: Exposure to malathion is sufficient to reduce abundance via reduction in prey availability (primarily salmonids and other fish)

Risk Hypothesis: Exposure to malathion is sufficient to reduce abundance via reduction in prey availability (primarily salmonids and other fish)		
Risk	**Confidence**	
High	**High**	

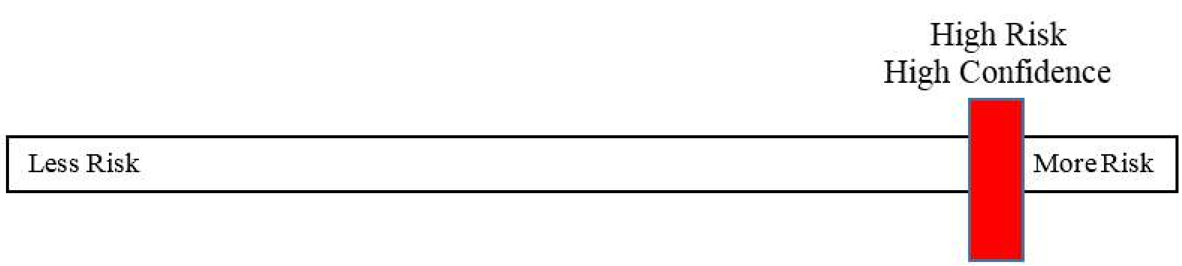
Effects analysis summary: Adult and juvenile Killer whales (southern resident DPS) are anticipated to experience reduced abundance via reductions in prey from exposure to malathion. The primary dietary item of the southern resident killer whale is salmon (predominantly Chinook). Chinook salmon populations have declined due to degradation of habitat, hydrology issues, harvest, and hatchery introgression; such reductions may require an increase in foraging effort. In addition, these prey contain environmental pollutants. These contaminants become concentrated at higher trophic levels and may lead to immune suppression or reproductive impairment. The overall risk to Killer whale, southern resident DPS from the effects of the action is high and the confidence associated with that risk is high.

National Marine Fisheries Service (NMFS) qualitatively evaluated long-term effects on the Southern Residents from the anticipated appreciable reduction in the likelihood of survival and recovery of all 28 Pacific salmon Evolutionarily Significant Units (ESUs)/ Distinct Population Segment (DPSs), and in particular, the nine Chinook salmon ESUs. We assessed the likelihood for localized depletions, and long-term implications for Southern Residents' survival and recovery, resulting from the increased risk of extinction of all listed Chinook salmon ESUs. In this way, NMFS can determine whether the increased likelihood of extinction of prey species is also likely to appreciably reduce the likelihood of survival and recovery of Southern Residents.

A reduction in prey would occur over time as abundance declined for the nine ESUs of Chinook salmon, along with the decline of lesser preferred prey ESUs/DPSs of other listed salmon. The continued depletion of these ESUs would also preclude the potential for their future recovery to healthy, more substantial numbers. Fewer populations contributing to Southern Residents' prey base will reduce the representation of diversity in life histories, resiliency in withstanding stochastic events, and redundancy to ensure there is a margin of safety for the salmon and Southern Residents to withstand catastrophic events.

The long-term reduction of the nine ESUs of Chinook salmon and other listed salmon and steelhead can lead to nutritional stress in the whales. Nutritional stress can lead to reduced body size and condition of individuals and can also lower reproductive and survival rates. Prey sharing would distribute more evenly the effects of prey limitation across individuals of the population that would otherwise be the case. Therefore, poor nutrition from the reduction of prey could contribute to additional mortality in this population. Food scarcity could also cause whales to draw on fat stores, mobilizing contaminants stored in their fat and affecting reproduction and immune function.

Differences in adult salmon life histories and locations of their natal streams likely affect the distribution of salmon across the Southern Residents' coastal range. The continued decline and potential extinction of the nine ESUs of Chinook salmon and other listed salmonids, and consequent interruption in the geographic continuity of salmon-bearing watersheds in the Southern Residents' coastal range, is likely to alter the distribution of migrating salmon and increase the likelihood of localized depletions in prey. This would have adverse effects on the Southern Residents' ability to meet their energy needs. A fundamental change in the prey base originating from the whales' geographic range is likely to result in Southern Residents abandoning areas in search of more abundant prey or expending substantial effort to find depleted prey resources. This potential increase in energy demands should have the same effect on an animal's energy budget as reductions in available energy, such as one would expect from reductions in prey.



14.62 Steller Sea Lion, Western DPS (Eumetopias jubatus)

Effects analysis summary: Adult and juvenile Guadalupe fur seals are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, fur seals may experience increased toxicity. The overall risk to Guadalupe fur seals from the effects of the action is low and the confidence associated with that risk is medium. The Low risk is due primarily to the small portion of the species' range within US territories. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats.

Exposure to malathion is sufficient to reduce abundance via reduction in prey availability (fish)	High	Low	Not Available	**Yes**
Exposure to malathion is sufficient to reduce ChE activity via dietary exposure (inverts and fish); the identified mechanism of toxicity	Low	Medium	Not Available	**No**
Exposure to malathion is sufficient to reduce ChE activity via dermal exposure; the identified mechanism of toxicity	Low	Medium	Not Available	**No**
Exposure to malathion is sufficient to reduce adult productivity via impairments to reproduction via dietary exposure (fish)	Low	Medium	Not Available	**No**

Effects analysis summary: Adult and juvenile Hawaiian monk seals are not anticipated to experience significant reductions in abundance or productivity (adults) from exposure to malathion in the marine environment. If exposed to formulated products and tank mixtures containing malathion, fur seals may experience increased toxicity. The overall risk to Hawaiian monk seals from the effects of the action is medium and the confidence associated with that risk is low. The lack in confidence is due primarily to the uncertainty in predicted malathion concentrations in coastal habitats.

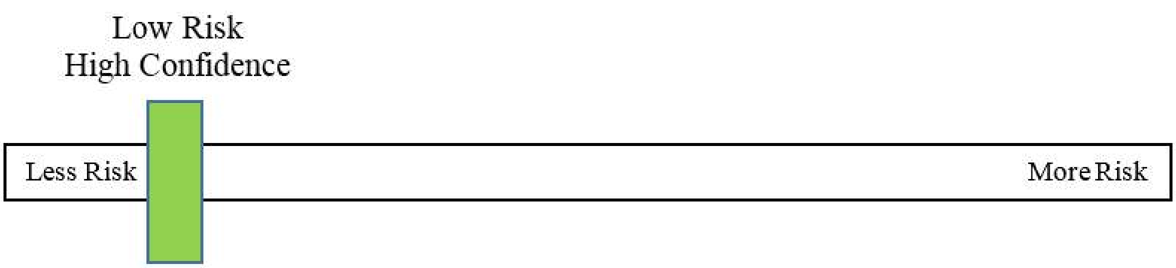
Effects analysis summary: Johnson's seagrass is not anticipated to experience significant reductions in abundance or productivity from exposure to malathion in the marine environment. The overall risk to Johnson's seagrass from the effects of the action is low and the confidence associated with that risk is high.



CHAPTER 15

DESIGNATED CRITICAL HABITAT EFFECTS ANALYSIS

CHLORPYRIFOS

TABLE OF CONTENTS

Page

15 CHLORPYRIFOS

15.1 Introduction

The National Marine Fisheries Service's (NMFS') critical habitat analysis determines whether the proposed action is likely to destroy or adversely modify critical habitat for ESA-listed species by examining potential reductions in the conservation value of the essential features of designated critical habitat. "Destruction or adverse modification" means a direct or indirect alteration that appreciably diminishes the value of designated critical habitat for the conservation of an ESA-listed species. Such alterations may include, but are not limited to, those that alter the physical or biological features (PBFs) essential to the conservation of a species or that preclude or significantly delay development of such features (50 C.F.R. §402.02).

In this section, NMFS evaluates the potential consequences to designated critical habitat from exposure to the stressors of the proposed action. A diagram of our analysis framework is shown in ***Figure 1***. It is similar in structure to the jeopardy analysis, but focuses on whether the proposed action is likely to destroy or adversely modify designated critical habitat for listed species. NMFS reviews the status of designated and proposed critical habitat affected by the proposed action separate from species effects by examining the condition and trends of the designated essential physical or biological features (PBFs) of critical habitat throughout the action area. We first determine whether critical habitat is likely to be exposed to the stressors of the proposed action (exposure profile). To conduct this analysis, we relied on R-plots showing expected pesticide concentrations in the species' designated critical habitat. If we find that critical habitat is likely to be exposed, we determined the relevant PBFs for each species' designated critical habitat that would be at risk from this proposed action and assess the consequences of that exposure on the quality, quantity, or availability of those PBFs (response profile) (Appendix C). We relied heavily on Crop Land Data Layers of crop uses provided by Environmental Protection Agency (EPA) and conducted an overlap of critical habitat analysis to determine exposure potential to designated critical habitat.

In all of the critical habitat designations that are exposed to the stressors of this action, water quality and forage (prey availability) are key attributes that are either designated as PBFs of the critical habitat, or are relevant to the PBFs. Water quality encompasses a range of typically measured parameters, including dissolved oxygen, temperature, turbidity, and presence of contaminants. Here, we use the presence of chemical contaminants as an indicator of degraded water quality. The proposed action would degrade water quality by introducing chlorpyrifos, diazinon, malathion, and other associated chemicals into designated critical habitats. Therefore, we use the pesticide concentrations likely to adversely affect listed species or prey (e.g. invertebrates and juvenile fish) as measures of degraded water quality. We also note that the PBF's for most of the critical habitats at issue include availability and quality of prey. The three a.i.s are expected to affect prey at concentrations within the range predicted to occur in most freshwater and estuarine habitats by exposure models. This analysis is conducted by comparing toxicity information (e.g., aquatic invertebrate LC_{50} values) provided in EPA's "Effects Characterization" in their BE, with expected pesticide concentrations derived from R-plots using data from EPA's MagTool.

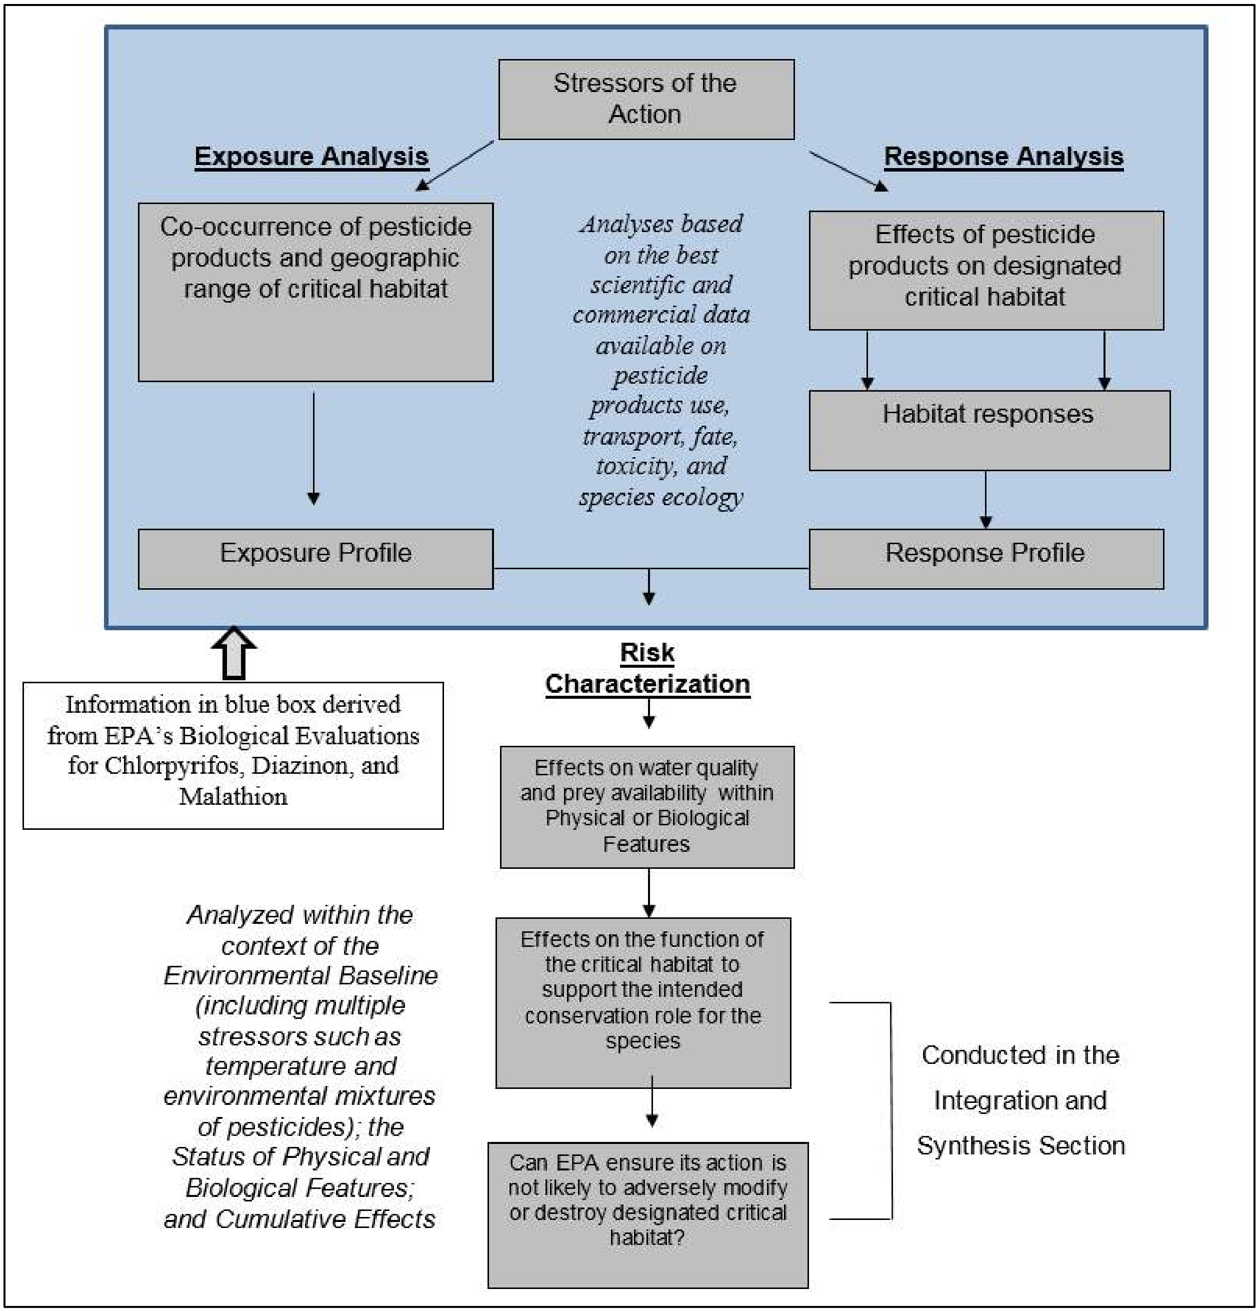


Figure 1. Assessment Framework for Designated Critical Habitat

We translated each PBF into a risk hypothesis to assess potential impacts on designated critical habitat. The analysis of risk hypotheses is based on: 1) the likely concentrations of the three pesticides that would be observed in critical habitat; and 2) the response of PBFs to those anticipated concentrations.

The action area for this Opinion encompasses all designated critical habitat for listed species within the continental U.S., Hawaii, Alaska, and U.S. Protectorates. These species include Pacific salmonids in Washington, Oregon, California and Idaho. As the species of salmonids addressed in this Opinion have similar life history characteristics, they share many of the same

PBFs. These PBFs include sites that support one or more life stages and contain physical or biological features essential to the conservation of the evolutionarily significant unit (ESU) or distinct population segment (DPS). PBFs include freshwater spawning sites, freshwater rearing sites, freshwater migration corridors, estuarine areas, nearshore marine areas, and offshore marine areas. Other species include two Puget Sound rockfish species, eulachon, two sturgeon species, two species of corals, black abalone, several species of sea turtles, Southern Resident Killer Whale, two pinniped species, Johnson's seagrass, and Smalltooth sawfish. For each of these species we determined the relevant PBFs that would be affected by the proposed action. Descriptions of species' designated critical habitats and associated PBFs are provided in Appendix C.

Water quality and prey availability in freshwater and estuarine areas may be susceptible to pesticide effects where critical habitat overlaps with or is adjacent to use sites. Effects to water quality and prey availability will be evaluated to determine the likelihood of reducing the quality of freshwater, estuarine, and nearshore marine areas. Given the use and environmental fate profile of the pesticide formulations containing these active ingredients, we do not expect offshore marine areas to be directly affected. Therefore, a risk hypothesis was not developed for this area and further evaluation of this PBF is not warranted.

Sufficient water quality is a necessary attribute of many aquatic PBFs to support the conservation role of designated critical habitat, and water quality unimpaired by toxins is necessary to the PBFs of the critical habitats affected by the stressors of this action. For example, all species of juvenile salmon need clean cold water. Clean and cold water is essential support for producing abundant prey for salmonid growth and development. This is also true for green sturgeon. Eggs and larvae develop in freshwater. Development of early life stages is affectd by water flow and temperature. Juvenile sturgeon rear and feed in fresh and estuarine waters from one to 4 years prior to dispersing into marine waters as subadults. During this time, their growth and development relies on adequate water quality to support abundant prey production. Water quality is clearly degraded when pesticides and other stressors of the action reach levels in habitat that are sufficient to adversely affect aquatic organisms and reduce individual fitness of exposed Endangered Species Act (ESA)-listed species. Impacts to species fitness were evaluated earlier in the document and these impacts are used as indicators of degraded water quality. We evaluate exposure and effect concentrations presented in EPA's BEs to determine whether PBFs are impacted.

We also evaluate effects on prey because forage is an essential attribute of many PBFs. Freshwater juvenile rearing and migratory habitats as well as estuarine and nearshore marine areas must provide sufficient forage to support growth and development of the listed species. Reductions in the abundance of prey items can decrease the quality of rearing, migration, and estuarine PBFs, as less available food will support fewer individuals. Reductions in prey can reduce a PBF's potential to support species (juvenile development, growth, maturation, survival), thereby reducing the carrying capacity of critical habitat. We evaluated the toxicity assessment endpoints including prey and fish survival (EC_{50}/LC_{50}) to determine whether expected concentrations of the stressors of the action are sufficient to affect PBFs of species critical habitats.

Designated critical habitat is located within the action area. Many freshwater areas overlap with the allowable uses of the three a.i.'s. The stressors of the action contaminate these habitats via drift and runoff (including from irrigation returns), and to a lesser extent from atmospheric deposition. Once in species habitats, the three active ingredients persist for varying periods of time, depending in part on the chemical, biological, and physical environment of the contaminated aquatic habitats. The most persistent of the three, chlorpyrifos (soil half-life 171 days),[1] may accumulate in soils and contribute to aquatic loading via runoff months later affecting organisms beyond those exposed initially from application events. Expected concentrations of other/inert ingredients and adjuvants added to formulations prior to application remain unknown, and are an identified data gap.

We use the toxicity information provided in the BEs and presented earlier in the Effects Analysis (Chapters 12, 13, and 14) to evaluate the scientific lines of evidence that support or refute risk hypotheses developed for designated and proposed critical habitats. Freshwater spawning and rearing sites, migration corridors, estuarine areas, and nearshore marine areas within designated critical habitats are likely to be exposed to the stressors of the action over the 15-year registration duration. We estimate expected concentrations and durations of exposure for these habitats based on pesticide use information, surface water monitoring data, EPA modeling estimates, and NMFS modeling estimates.

For each risk hypothesis in ***Table 1*** (also refer to Appendix E for specific risk hypotheses for each species PBFs relevant to this analysis) we qualitatively weigh the evidence to determine whether the PBF attributes of water quality and prey availability are affected for each species designated critical habitat. Water quality is degraded when pesticides and other stressors of the action reach levels in habitat that are sufficient to adversely affect aquatic organisms and reduce individual fitness of exposed ESA-listed species (this was evaluated earlier in the document). We ultimately determine whether the degradation of water quality and reduction in prey availability within freshwater spawning and rearing sites, migration corridors, estuarine areas, and nearshore marine areas will rise to the level expected to reduce the intended conservation role of designated critical habitats. This analysis is conducted by evaluating toxicity information (e.g., aquatic invertebrate LC50 values), as well as by characterizing the likelihood of exposure within the designated critical habitat. Likelihood of exposure for critical habitat considers three factors: 1) percent overlap; 2) chemical persistence, and; 3) number of repeated applications allowed. See Chapter 3 for a description of how these factors are considered to determine the overall likelihood of exposure.

See Chapters 22 – 24 (Integration and Synthesis for Designated Critical Habitat*)* for the final conclusion of whether EPA's proposed action with end-use products containing chlorpyrifos, diazinon, or malathion are likely to adversely modify or destroy a species' designated or proposed critical habitat.

Table 1. Generalized risk hypotheses for relevant PBF's.

Risk hypothesis for relevant physical or biological features
1. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in freshwater spawning sites.
2. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in freshwater rearing sites.

[1] Diazinon soil half-life is 34 days, malathion soil half-life is 1 day.

3. Exposure to the stressors of the action is sufficient to degrade water quality, and/or reduce prey resources in freshwater migratory corridors.
4. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in estuarine areas.
5. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in nearshore marine areas.

The following sections provide the chemical-specific assessments of risk hypotheses for each designated critical habitats involved in this consultation (defined by the action area).

Table 3. Water quality risk hypothesis; chum salmon, Columbia River ESU designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of chlorpyrifos-containing products occur within Chum salmon, Columbia River ESU designated critical habitat. Fourteen use site categories, totaling more than 852,477 acres (over 58% of acres) are currently present. In addition, proposed labels for chlorpyrifos allow for mosquito control and wide area use, both of which can be applied to 100% of the species designated critical habitat. The anticipated chlorpyrifos levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, chlorpyrifos and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.		
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.

Designated Critical Habitat; Risk Hypotheses	**R-plot Derived**		**Risk Hypothesis Supported?**
	Risk	**Confidence**	**Yes/No**
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	High	High	Yes

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Columbia River Chum Salmon. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We have greater confidence in the risk determinations associated with the freshwater habitats than we do in the estuarine and nearshore habitats. Overall the risk is high and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Table 12. Water quality risk hypothesis; Chinook, Central Valley spring-run ESU; designated critical habitat.

Endpoint: Water Quality
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of chlorpyrifos-containing products occur within the designated critical habitat of Chinook, Central Valley spring-run ESU. Sixteen use site categories, totaling more than 2,211,697 acres (over 65% of acres) are currently present. In addition, proposed labels for chlorpyrifos allow for mosquito control and wide area use, both of which can be applied to 100% of the species designated critical habitat. The anticipated chlorpyrifos levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur,

chlorpyrifos and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.

Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.		
Risk	**Confidence**	
High	**High**	

Table 13. Effects analysis summary table; Chinook, Central Valley spring-run ESU; designated critical habitat.

	R-plot Derived		**Risk Hypothesis Supported? Yes/No**
Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Central Valley Spring-run Chinook. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical

habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Upper Willamette River Chinook. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Table 36. Water quality risk hypothesis; Coho, Central California Coast ESU; designated critical habitat.

Endpoint: Water Quality
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of chlorpyrifos-containing products occur within the designated critical habitat of Central California Coast Coho. Sixteen use site categories, totaling more than 1,351,070 acres (over 35% of acres) are currently present. In addition, proposed labels for chlorpyrifos allow for mosquito control and wide area use, both of which can be applied to 100% of the species designated critical habitat. The anticipated chlorpyrifos levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, chlorpyrifos and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.

Table 59. Water quality risk hypothesis; Steelhead, Central California coast DPS;designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of chlorpyrifos-containing products occur within the designated critical habitat of Steelhead, Central California coast ESU. Sixteen use site categories, totaling more than 3,314,460 acres (over 45% of acres) are currently present. In addition, proposed labels for chlorpyrifos allow for mosquito control and wide area use, both of which can be applied to 100% of the species designated critical habitat. The anticipated chlorpyrifos levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, chlorpyrifos and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.		
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.

Table 79. Water quality risk hypothesis; Steelhead, Snake River basin DPS; designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of chlorpyrifos-containing products occur within the designated critical habitat of Steelhead, Snake River basin DPS. Seventeen use site categories, totaling more than 9,136,811 acres (over 52% of acres) are currently present. In addition, proposed labels for chlorpyrifos allow for mosquito control and wide area use, both of which can be applied to 100% of the species designated critical habitat. The anticipated chlorpyrifos levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, chlorpyrifos and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.

Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Snake River Basin Steelhead. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Table 102. Water quality risk hypothesis; Green Sturgeon, Southern DPS; designated critical habitat.

Endpoint: Water Quality
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of chlorpyrifos-containing products occur within the designated critical habitat of Green sturgeon. Seventeen use site categories, totaling more than 5,076,959 acres (over 49% of acres) are currently present. In addition, proposed labels for chlorpyrifos allow for mosquito control and wide area use, both of which can be applied to 100% of the species designated critical habitat. The anticipated chlorpyrifos levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures

occur, chlorpyrifos and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.

Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.

Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater habitats.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of prey in freshwater habitats.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in estuarine habitats.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in estuarine habitats.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in coastal habitats.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in coastal habitats.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Green Sturgeon (Southern DPS). The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in the estuarine and nearshore habitats.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in the estuarine and nearshore habitats.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect some physical or biological features (PBFs) within estuarine and nearshore habitats. However, we have low confidence in the EECs predicted for the nearshore habitats of Gulf Sturgeon. Within the nearshore and estuarine portions of their range, we do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Atlantic Sturgeon, Carolina DPS. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Table 126. Water quality risk hypothesis; Atlantic Sturgeon, South Atlantic DPS; designated critical habitat.

Endpoint: Water Quality
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of chlorpyrifos-containing products occur within the designated critical habitat of Atlantic sturgeon, South Atlantic DPS. Sixteen use site categories, totaling more than 2,380,127 acres (over 50% of acres) are currently present. In addition, proposed labels for chlorpyrifos allow for mosquito control and wide area use, both of which can be applied to 100% of the species designated critical habitat. The anticipated chlorpyrifos levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the

proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation.

Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect relevant physical or biological features within estuarine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats of Yelloweye Rockfish (Puget Sound/Georgia Basin DPS). Within the nearshore and estuarine portions of their range, we do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of Loggerhead Sea Turtle (NW Atlantic Ocean DPS). However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Table 151. Water quality risk hypothesis; Killer whale, Southern resident DPS; designated critical habitat.

Endpoint: Water Quality

Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of chlorpyrifos-containing products occur in proximity to the designated critical habitat of Killer whale, Southern resident DPS. Sixteen use site categories, totaling more than 1,573,064 acres (over 33% of acres) are currently present. In addition, proposed labels for chlorpyrifos allow for mosquito control and wide area use, both of which can be applied to 100% of the species designated critical habitat. The anticipated chlorpyrifos levels in designated critical habitat are not sufficient to cause adverse effects to killer whales.		
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.		
Risk	**Confidence**	
Low	**High**

Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	
Direct exposure to the stressors of the action within designated critical habitat is sufficient to reduce the conservation value via reductions in prey (fish).	Low	High	No
Exposure to the stressors of the action outside of designated critical habitat is sufficient to in-directly reduce the conservation value via reductions in prey availability (Chinook salmon).	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.	Low	High	No

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate stressors of the action will directly affect physical or biological features (PBFs). Reductions in suitable prey (within designated critical habitat) and degradation of water quality are unlikely throughout designated critical habitat of Southern Resident Killer Whale. However, indirectly, prey species (salmon) will be adversely affected by exposures anticipated in their freshwater habitats. The likelihood and magnitude of toxic effects will reduce the overall conservation value of designated critical habitat by reducing the availability of these important prey. We find that the overall risk is medium and the confidence associated with that risk is medium over the 15-year duration of the action.

Medium Risk

Exposure to the stressors of the action is sufficient to reduce prey.	Medium	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

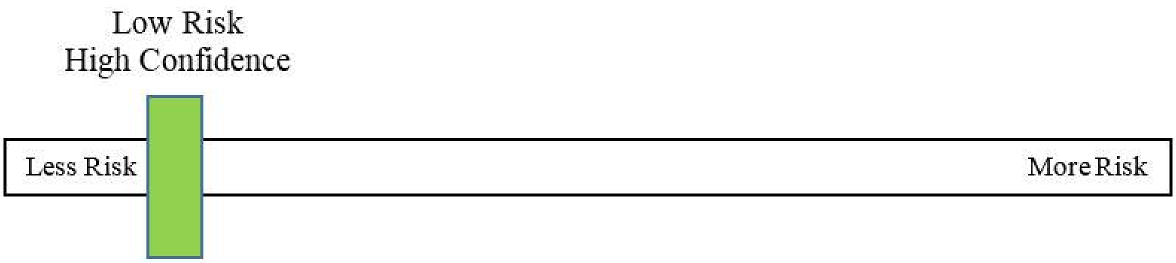
The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of Hawaiian Monk Seal. However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

15.51 Johnson's Seagrass Designated Critical Habitat

Water quality, in terms of water clarity for photosynthesis, is a physical or biological features identified in Johnson's seagrass designated critical habitat. However, we do not anticipate exposures from the stressors of the action to be sufficient to reduce conservation values of this PBF. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.



15.52 Summary of the Effects of the Action on Physical or Biological Features

We conclude that the available information on exposure and response of aquatic habitats to the stressors of the action supports risk hypotheses for many of the species. Table 155 summarizes for chlorpyrifos and for the species habitats where risk hypotheses are supported. We expect water quality and prey abundance to be reduced in spawning, rearing, migratory, estuarine, or nearshore marine habitats for many of the species' designated critical habitats. Next, within the *Integration and Synthesis for Designated Critical Habitat* section, we evaluate whether these adverse changes to PBFs affect the conservation value of designated critical habitat.

CHAPTER 16

DESIGNATED CRITICAL HABITAT EFFECTS ANALYSIS

DIAZINON

TABLE OF CONTENTS

Page

16 DIAZINON

16.1 Introduction

The National Marine Fisheries Services (NMFS') critical habitat analysis determines whether the proposed action is likely to destroy or adversely modify critical habitat for Endangered Species Act (ESA)-listed species by examining potential reductions in the conservation value of the essential features of designated critical habitat. "Destruction or adverse modification" means a direct or indirect alteration that appreciably diminishes the value of designated critical habitat for the conservation of an ESA-listed species. Such alterations may include, but are not limited to, those that alter the physical or biological features (PBFs) essential to the conservation of a species or that preclude or significantly delay development of such features (50 C.F.R. §402.02).

In this section, NMFS evaluates the potential consequences to designated critical habitat from exposure to the stressors of the proposed action. A diagram of our analysis framework is shown in ***Figure 1***. It is similar in structure to the jeopardy analysis, but focuses on whether the proposed action is likely to destroy or adversely modify designated critical habitat for listed species. NMFS reviews the status of designated and proposed critical habitat affected by the proposed action separate from species effects by examining the condition and trends of the designated essential physical or biological features (PBFs) of critical habitat throughout the action area. We first determine whether critical habitat is likely to be exposed to the stressors of the proposed action (exposure profile). To conduct this analysis, we relied on R-plots showing expected pesticide concentrations in the species' designated critical habitat. If we find that critical habitat is likely to be exposed, we determined the relevant PBFs for each species' designated critical habitat that would be at risk from this proposed action and assess the consequences of that exposure on the quality, quantity, or availability of those PBFs (response profile) (Appendix C). We relied heavily on EPA provided Crop Land Data Layers of crop uses and conducted an overlap of critical habitat analysis to determine exposure potential to designated critical habitat.

In all of the critical habitat designations that are exposed to the stressors of this action, water quality and forage (prey availability) are key attributes that are either designated as PBFs of the critical habitat, or are relevant to the PBFs. Water quality encompasses a range of typically measured parameters, including dissolved oxygen, temperature, turbidity, and presence of contaminants. Here, we use the presence of chemical contaminants as an indicator of degraded water quality. The proposed action would degrade water quality by introducing chlorpyrifos, diazinon, malathion, and other associated chemicals into designated critical habitats. Therefore, we use the pesticide concentrations likely to adversely affect listed species or prey (e.g. invertebrates and juvenile fish) as measures of degraded water quality. We also note that the PBF's for most of the critical habitats at issue include availability and quality of prey. The three a.i.s are expected to affect prey at concentrations within the range predicted to occur in most freshwater and estuarine habitats by exposure models. This analysis is conducted by comparing toxicity information (e.g., aquatic invertebrate LC_{50} values) provided in EPA's "Effects Characterization" in their BE, with expected pesticide concentrations derived from R-plots using data from EPA's MagTool.

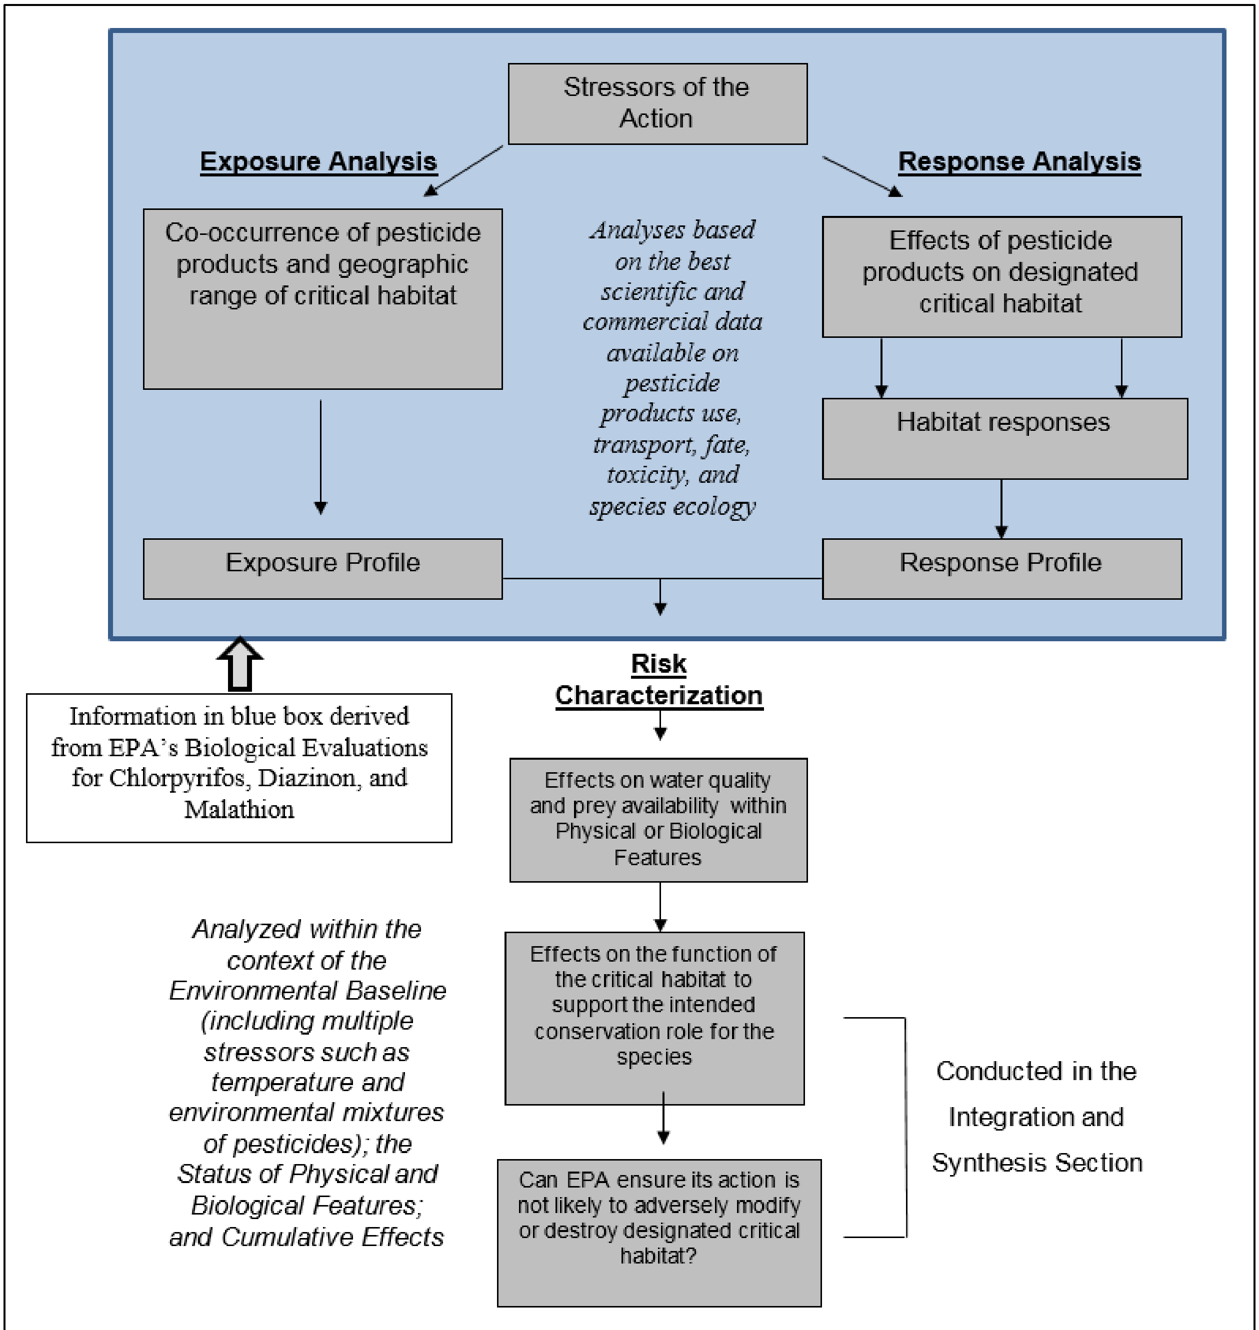

Figure 1. Assessment Framework for Designated Critical Habitat

Figure 1. Assessment Framework for Designated Critical Habitat

We translated each PBF into a risk hypothesis to assess potential impacts on designated critical habitat. The analysis of risk hypotheses is based on: 1) the likely concentrations of the three pesticides that would be observed in critical habitat; and 2) the response of PBFs to those anticipated concentrations.

The action area for this Opinion encompasses all designated critical habitat for listed species within the continental U.S., Hawaii, Alaska, and U.S. Protectorates. These species include Pacific salmonids in Washington, Oregon, California and Idaho. As the species of salmonids addressed in this Opinion have similar life history characteristics, they share many of the same PBFs. These PBFs include sites that support one or more life stages and contain physical or biological features essential to the conservation of the Evolutionarily Significant Unit (ESU)/ Distinct Population Segment (DPS). PBFs include freshwater spawning sites, freshwater rearing sites, freshwater migration corridors, estuarine areas, nearshore marine areas, and offshore marine areas. Other species include two Puget Sound rockfish species, eulachon, two sturgeon species, two species of corals, black abalone, several species of sea turtles, Southern Resident Killer Whale, two pinniped species, Johnson's seagrass, and Smalltooth sawfish. For each of these species we determined the relevant PBFs that would be affected by the proposed action. Descriptions of species' designated critical habitats and associated PBFs are provided in Appendix C.

Water quality and prey availability in freshwater and estuarine areas may be susceptible to pesticide effects where critical habitat overlaps with or is adjacent to use sites. Effects to water quality and prey availability will be evaluated to determine the likelihood of reducing the quality of freshwater, estuarine, and nearshore marine areas. Given the use and environmental fate profile of the pesticide formulations containing these active ingredients, we do not expect offshore marine areas to be directly affected. Therefore, a risk hypothesis was not developed for this area and further evaluation of this PBF is not warranted.

Sufficient water quality is a necessary attribute of many aquatic PBFs to support the conservation role of designated critical habitat, and water quality unimpaired by toxins is necessary to the PBFs of the critical habitats affected by the stressors of this action. For example, all species of juvenile salmon need clean cold water. Clean and cold water is essential support for producing abundant prey for salmonid growth and development. This is also true for green sturgeon. Eggs and larvae develop in freshwater. Development of early life stages is affected by water flow and temperature. Juvenile sturgeon rear and feed in fresh and estuarine waters from one to 4 years prior to dispersing into marine waters as subadults. During this time, their growth and development relies on adequate water quality to support abundant prey production. Water quality is clearly degraded when pesticides and other stressors of the action reach levels in habitat that are sufficient to adversely affect aquatic organisms and reduce individual fitness of exposed ESA-listed species. Impacts to species fitness were evaluated earlier in the document and these impacts are used as indicators of degraded water quality. We evaluate exposure and effect concentrations presented in the Environmental Protection Agency's (EPA's) BEs to determine whether PBFs are impacted.

We also evaluate effects on prey because forage is an essential attribute of many PBFs. Freshwater juvenile rearing and migratory habitats as well as estuarine and nearshore marine areas must provide sufficient forage to support growth and development of the listed species. Reductions in the abundance of prey items can decrease the quality of rearing, migration, and estuarine PBFs, as less available food will support fewer individuals. Reductions in prey can reduce a PBF's potential to support species (juvenile development, growth, maturation, survival), thereby reducing the carrying capacity of critical habitat. We evaluated the toxicity assessment endpoints including prey and fish survival (EC_{50}/LC_{50}) to determine whether expected concentrations of the stressors of the action are sufficient to affect PBFs of species critical habitats.

Designated critical habitat is located within the action area. Many freshwater areas overlap with the allowable uses of the three a.i.'s. The stressors of the action contaminate these habitats via drift and runoff (including from irrigation returns), and to a lesser extent from atmospheric deposition. Once in species habitats, the three active ingredients persist for varying periods of time, depending in part on the chemical, biological, and physical environment of the contaminated aquatic habitats. The most persistent of the three, chlorpyrifos (soil half-life 171 days),[1] may accumulate in soils and contribute to aquatic loading via runoff months later affecting organisms beyond those exposed initially from application events. Expected concentrations of other/inert ingredients and adjuvants added to formulations prior to application remain unknown, and are an identified data gap.

We use the toxicity information provided in the BEs and presented earlier in the Effects Analysis Chapters (Chapters 12, 13, and 14) to evaluate the scientific lines of evidence that support or refute risk hypotheses developed for designated and proposed critical habitats. Freshwater spawning and rearing sites, migration corridors, estuarine areas, and nearshore marine areas within designated critical habitats are likely to be exposed to the stressors of the action over the 15-year registration duration. We estimate expected concentrations and durations of exposure for these habitats based on pesticide use information, surface water monitoring data, EPA modeling estimates, and NMFS modeling estimates.

For each risk hypothesis in ***Table 1*** (also refer to Appendix E for specific risk hypotheses for each species PBFs relevant to this analysis) we qualitatively weigh the evidence to determine whether the PBF attributes of water quality and prey availability are affected for each species designated critical habitat. Water quality is degraded when pesticides and other stressors of the action reach levels in habitat that are sufficient to adversely affect aquatic organisms and reduce individual fitness of exposed ESA-listed species (this was evaluated earlier in the document). We ultimately determine whether the degradation of water quality and reduction in prey availability within freshwater spawning and rearing sites, migration corridors, estuarine areas, and nearshore marine areas will rise to the level expected to reduce the intended conservation role of designated critical habitats. This analysis is conducted by evaluating toxicity information (e.g., aquatic invertebrate LC50 values), as well as by characterizing the likelihood of exposure within the designated critical habitat. Likelihood of exposure for critical habitat considers three factors: 1) percent overlap; 2) chemical persistence, and; 3) number of repeated applications allowed. See Chapter 3 for a description of how these factors are considered to determine the overall likelihood of exposure.

See Chapters 22 – 24 (Integration and Synthesis for Designated Critical Habitat) for the final conclusion of whether EPA's proposed action with end-use products containing chlorpyrifos, diazinon, or malathion are likely to adversely modify or destroy a species' designated or proposed critical habitat.

[1] Diazinon soil half-life is 34 days, malathion soil half-life is 1 day.

Table 1. Generalized risk hypotheses for relevant PBF's.

Risk hypothesis for relevant physical or biological features
1. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in freshwater spawning sites.
2. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in freshwater rearing sites.
3. Exposure to the stressors of the action is sufficient to degrade water quality, and/or reduce prey resources in freshwater migratory corridors.
4. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in estuarine areas.
5. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in nearshore marine areas.

The following sections provide the chemical-specific assessments of risk hypotheses for each designated critical habitats involved in this consultation (defined by the action area).

16.2 Columbia River Chum Salmon (O. keta) Designated Critical Habitat

Low	**High**		

Table 3. Water quality risk hypothesis; chum salmon, Columbia River ESU designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. The anticipated diazinon levels in designated critical habitat may be sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth may occur. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, diazinon and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates. Toxic concentrations may occur, however, authorized uses of diazinon-containing products occur minimally within Columbia River Chum designated critical habitat. Three use site categories, totaling approximately 3,154 acres (less than one percent of acres) are currently present.

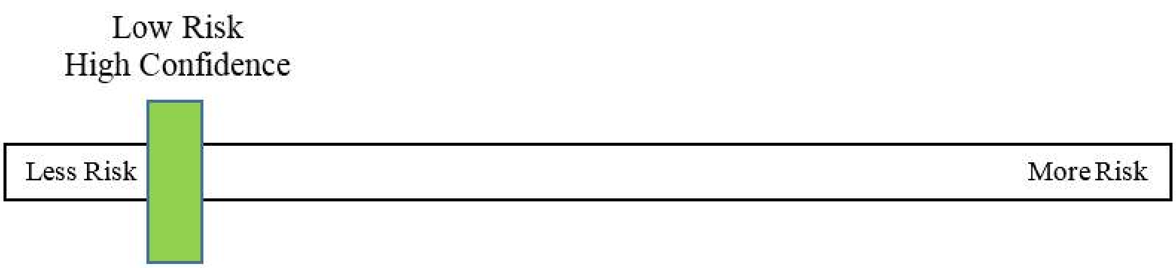
quality and/or reductions in prey in nearshore marine areas.			

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate that the stressors of the action will negatively affect physical and biological features (PBFs). Neither reductions in prey, nor degradation of water quality are likely throughout designated critical habitat of Columbia River Chum Salmon. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. We have greater confidence in the risk determinations associated with the freshwater habitats than we do in the estuarine and nearshore habitats. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.



16.3 Hood Canal summer-run Chum (O. keta) Designated Critical Habitat

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	Medium	Medium	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	Medium	Medium	Yes

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	Medium	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	Medium	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a medium likelihood that the stressors of the action will negatively affect physical and biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of California Coastal Chinook. The magnitude of toxic effects may result in some adverse effects. Due to the extent of diazinon-containing uses, we anticipate the overall conservation value of designated critical habitat to decrease moderately. We find that the overall risk is medium and the confidence associated with that risk is medium over the 15-year duration of the action.

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water	High	High	Yes

quality, natural cover, and/or reductions in prey in freshwater migratory corridors.			
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical and biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Central Valley Spring-run Chinook. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Table 15. Water quality risk hypothesis; Chinook, Lower Columbia River ESU; designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. The anticipated diazinon levels in designated critical habitat may be sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth may occur. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, diazinon and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates. Toxic concentrations may occur, however, authorized uses of diazinon-containing products occur minimally within Lower Columbia River Chinook designated critical habitat. Three use site categories, totaling approximately 17,729 acres (less than one percent of acres) are currently present.		
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	Low	Medium	No

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate that the stressors of the action will negatively affect physical and biological features (PBFs). Neither reductions in prey, nor degradation of water quality are likely throughout designated critical habitat of Lower Columbia River Chinook. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. We have greater confidence in the risk determinations associated with the freshwater habitats than we do in the estuarine and nearshore habitats. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	Low	High	No
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water	Low	High	No

quality, natural cover, and/or reductions in prey in freshwater migratory corridors.			
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	Low	Medium	No
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	Low	Medium	No

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate that the stressors of the action will negatively affect physical and biological features (PBFs). Neither reductions in prey, nor degradation of water quality are likely throughout designated critical habitat of Lower Columbia River Coho. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. We have greater confidence in the risk determinations associated with the freshwater habitats than we do in the estuarine and nearshore habitats. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Table 42. Water quality risk hypothesis; Coho, Oregon coast ESU; designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. The anticipated diazinon levels in designated critical habitat may be sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth may occur. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, diazinon and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates. Toxic concentrations may occur, however, authorized uses of diazinon-containing products occur minimally within Oregon Coast coho designated critical habitat. Three use site categories, totaling approximately 1,024 acres (less than one percent of acres) are currently present.

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	Low	Medium	No

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate that the stressors of the action will negatively affect physical and biological features (PBFs). Neither reductions in prey, nor degradation of water quality are likely throughout designated critical habitat of Lower Columbia River Steelhead. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. We have greater confidence in the risk determinations associated with the freshwater habitats than we do in the estuarine and nearshore habitats. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Designated Critical Habitat Effects Analysis Summary:

We anticipate a medium likelihood that the stressors of the action will negatively affect physical and biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Middle Columbia River Steelhead. The magnitude of toxic effects may result in some adverse effects. Due to the extent of diazinon-containing uses, we anticipate the overall conservation value of designated critical habitat to decrease moderately.

We find that the overall risk is medium and the confidence associated with that risk is medium over the 15-year duration of the action.

Low	**High**		

Table 71. Water quality risk hypothesis; Steelhead, Northern California DPS; designated critical habitat.

Endpoint: Water Quality
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. The anticipated diazinon levels in designated critical habitat may be sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth may occur. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, diazinon and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates. Toxic concentrations may occur, however, authorized uses of diazinon-containing products occur minimally within northern California steelhead designated critical habitat. Three use site categories, totaling approximately 223 acres (less than one percent of acres) are currently present.

Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.		
Risk	**Confidence**	
Low	**High**	

Table 72. Effects analysis summary table; Steelhead, Northern California DPS; designated critical habitat.

Designated Critical Habitat; Risk Hypotheses	R-plot Derived Risk	R-plot Derived Confidence	Risk Hypothesis Supported? Yes/No
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	Low	High	No
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	Low	High	No
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	Low	High	No
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	Low	High	No
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	Low	High	No

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate that the stressors of the action will negatively affect physical and biological features (PBFs). Neither reductions in prey, nor degradation of water quality are likely throughout designated critical habitat of Northern California Steelhead. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. We have greater confidence in the risk determinations associated with the freshwater habitats than we do in the estuarine and nearshore habitats. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Designated Critical Habitat; Risk Hypotheses	R-plot Derived		Risk Hypothesis Supported? Yes/No
	Risk	**Confidence**	
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater and estuarine habitats.	Low	High	No
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in freshwater and estuarine habitats.	Low	High	No
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in nearshore and offshore habitats.	Low	Low	No
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in nearshore and offshore habitats.	Low	Low	No

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate that the stressors of the action will negatively affect physical and biological features (PBFs). Neither reductions in prey, nor degradation of water quality are likely throughout designated critical habitat of Eulachon (Southern DPS). The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. We have greater confidence in the risk determinations associated with the freshwater habitats than we do in the estuarine and nearshore habitats. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in coastal habitats.	Medium	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a medium likelihood that the stressors of the action will negatively affect physical and biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Green Stugeon (Southern DPS). The magnitude of toxic effects may result in some adverse effects. Due to the extent of diazinon-containing uses, we anticipate the overall conservation value of designated critical habitat to decrease moderately. We find that the overall risk is medium and the confidence associated with that risk is medium over the 15-year duration of the action.

Low	**High**		

Table 130. Water quality risk hypothesis; Yelloweye rockfish, Puget Sound/Georgia Basin DPS; designated critical habitat.

Endpoint: Water Quality
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. The anticipated diazinon levels in designated critical habitat may be sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth may occur. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, diazinon and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates. Toxic concentrations may occur, however, authorized uses of diazinon-containing products occur minimally within yelloweye rockfish Puget Sound/Georgia Basin designated critical habitat. Three use site categories, totaling approximately 24,192 acres (less than one percent of acres) are currently present.

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate that the stressors of the action will negatively affect physical and biological features (PBFs). Neither reductions in prey, nor degradation of water quality are likely throughout designated critical habitat of Yelloweye Rockfish (Puget Sound/Georgia Basin DPS). The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. We have greater confidence in the risk determinations associated with the freshwater habitats than we do in the estuarine and nearshore habitats. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of Green Sea Turtle (North Atlantic DPS). However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

16.45 Hawksbill Sea Turtle Designated Critical Habitat

Risk Hypothesis: Direct exposure to the stressors of the action within designated critical habitat is sufficient to reduce prey (fish).			
Risk	**Confidence**		
Low	**High**		
Risk Hypothesis: Exposure to the stressors of the action outside of designated critical habitat is sufficient to in-directly reduce prey availability (Chinook salmon).			
Risk	**Confidence**	**Affecting the availability of prey species of sufficient quantity and quality. Jeopardy determinations were made for all ESU's of Chinook salmon with regard to the proposed action.**	
High	**High**		

Table 151. Water quality risk hypothesis; Killer whale, Southern resident DPS; designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of diazinon-containing products are minimal within proximity to the designated critical habitat of Killer whale, Southern resident DPS. Three use site categories, totaling more than 20,706 acres (less than one percent of acres) are currently present. The anticipated diazinon levels in designated critical habitat are not sufficient to cause adverse effects to killer whales.		
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.		
Risk	**Confidence**	
Low	**High**	

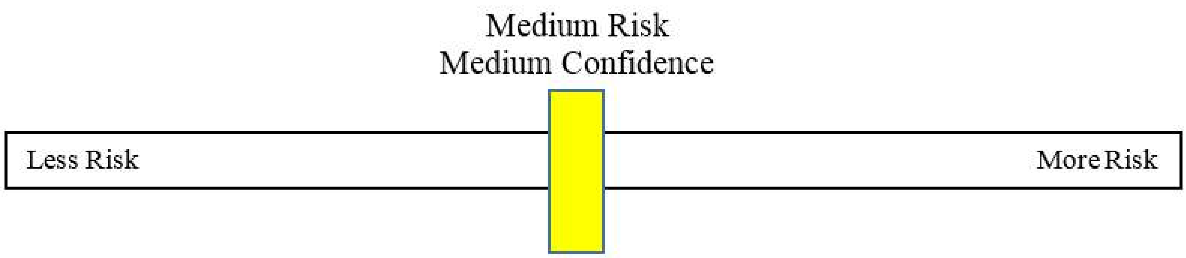
Table 152. Effects analysis summary table; Killer whale, Southern resident DPS; designated critical habitat.

	R-plot Derived		**Risk Hypothesis Supported? Yes/No**
Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	
Direct exposure to the stressors of the action within designated critical habitat is sufficient to reduce the conservation value via reductions in prey (fish).	Low	High	No
Exposure to the stressors of the action outside of designated critical habitat is sufficient to in-directly reduce the conservation value via reductions in prey availability (Chinook salmon).	High	High	Yes

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.	Low	High	No

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate stressors of the action will directly affect physical and biological features (PBFs). Reductions in suitable prey (within designated critical habitat) and degradation of water quality are unlikely throughout designated critical habitat of Southern Resident Killer Whale. However, indirectly, prey species (salmon) will be adversely affected by exposures anticipated in their freshwater habitats. The likelihood and magnitude of toxic effects will reduce the overall conservation value of designated critical habitat by reducing the availability of these important prey. We find that the overall risk is medium and the confidence associated with that risk is medium over the 15-year duration of the action.



16.49 Stellar Sea Lion (Western DPS) Designated Critical Habitat

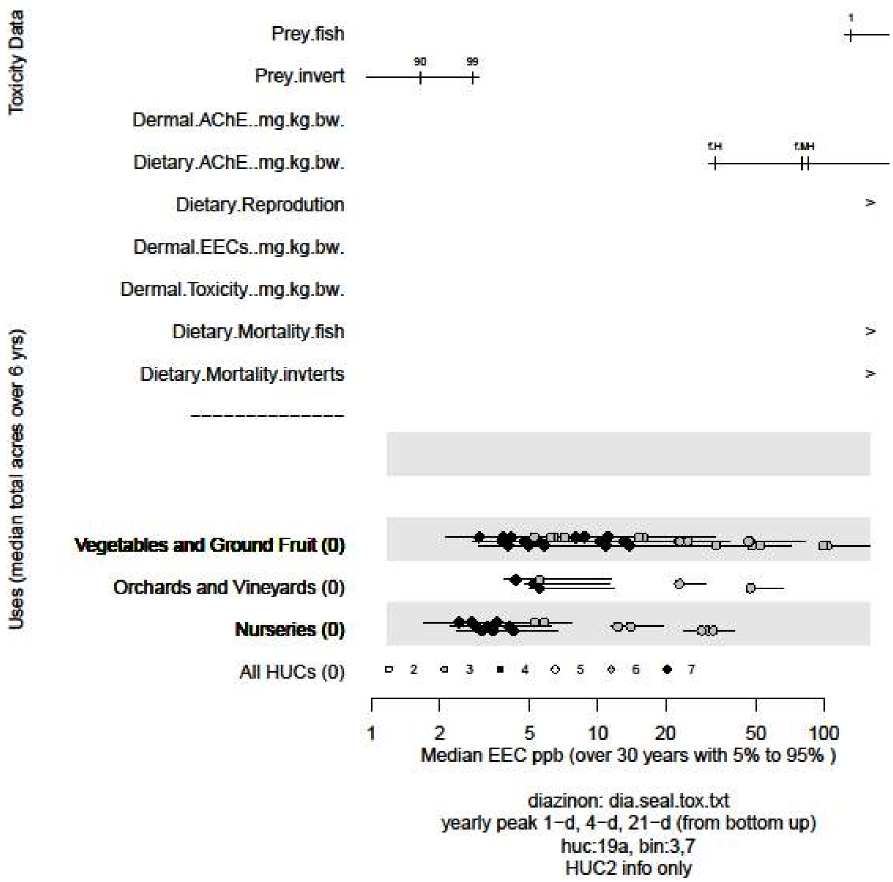


Figure 48. Effects analysis R-plot; Steller sealion, Western DPS designated critical habitat.

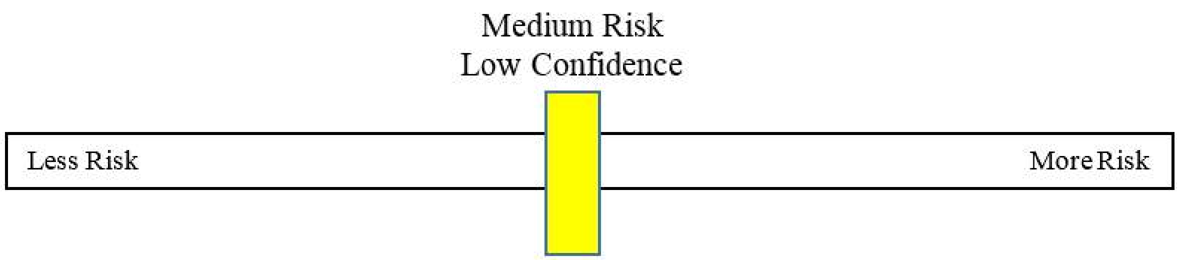
Table 153. Effects analysis summary table; Steller sealion, Western DPS; designated critical habitat.

	R-plot Derived		Risk Hypothesis Supported?
Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	**Yes/No**
Exposure to the stressors of the action is sufficient to reduce prey.	Medium	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat. However, we have low confidence in the EECs predicted for the marine nearshore habitats of Stellar Sea Lion (Western DPS). The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.



16.50 Hawaiin Monk Seal Designated Critical Habitat

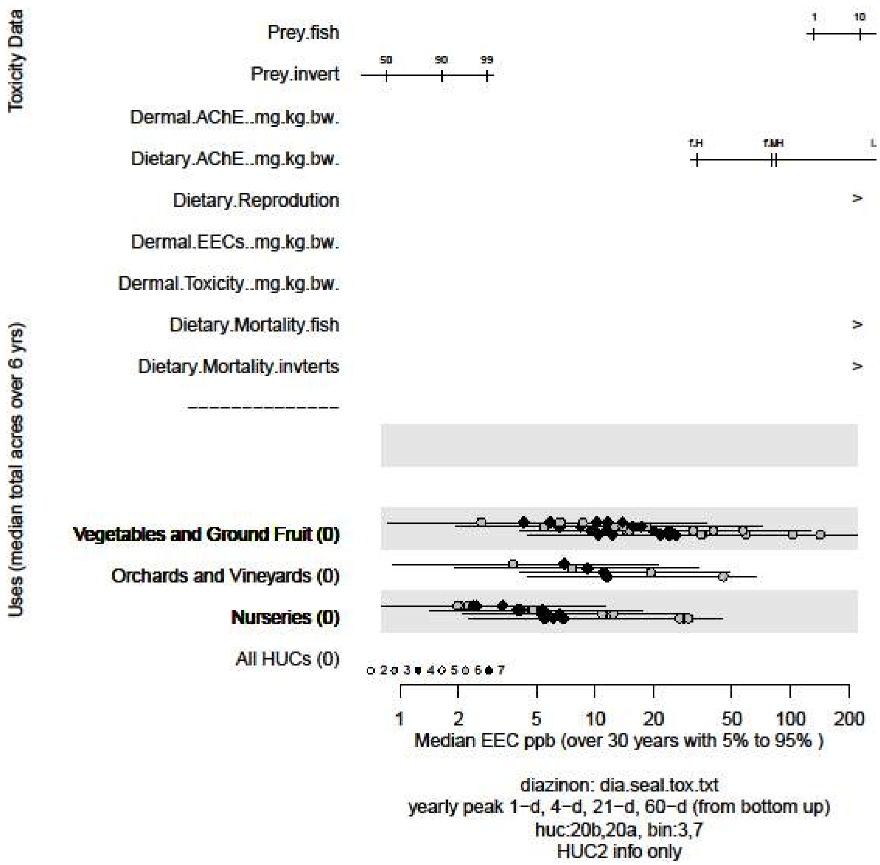


Figure 49. Effects analysis R-plot; Hawaiian Monk Seal designated critical habitat.

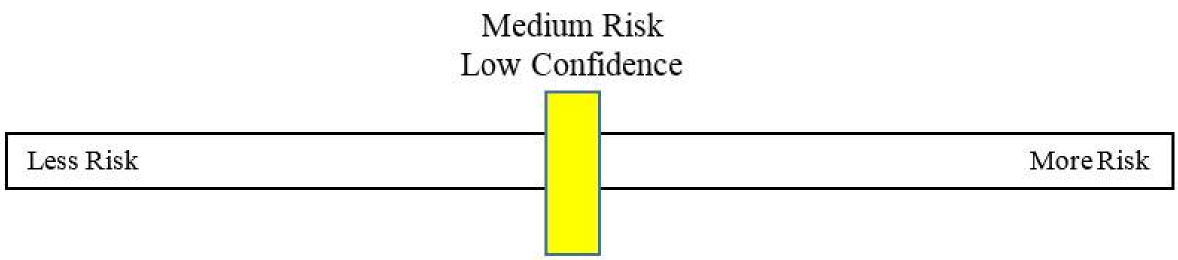
Table 154. Effects analysis summary table; Hawaiian Monk Seal designated critical habitat.

	R-plot Derived		**Risk Hypothesis Supported?**
Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	**Yes/No**
Exposure to the stressors of the action is sufficient to reduce prey.	Medium	Low	Yes

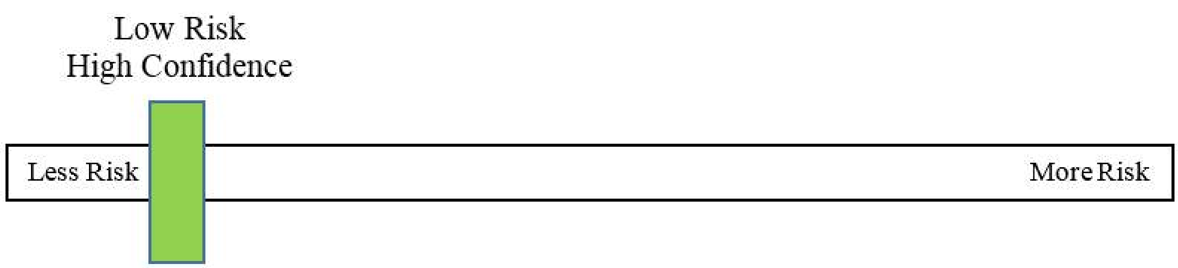
Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat. However, we have low confidence in the EECs predicted for the marine nearshore habitats of Hawaiin Monk Seal. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.



16.51 Johnson's Seagrass Designated Critical Habitat

Water quality is a physical and biological features identified in Johnson's seagrass designated critical habitat. However, we do not anticipate exposures from the stressors of the action to be sufficient to reduce conservation values of this PBF. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.



16.52 Summary of the Effects of the Action on Physical or Biological Features:

We conclude that the available information on exposure and response of aquatic habitats to the stressors of the action supports risk hypotheses for many of the species. Table 155 summarizes for diazinon and for the species habitats where risk hypotheses are supported. We expect water quality and prey abundance to be reduced in spawning, rearing, migratory, estuarine, or nearshore marine habitats for many of the species'designated critical habitats. Next, within the *Integration and Synthesis for Designated Critical Habitat* section, we evaluate whether these adverse changes to PBFs affect the conservation value of designated critical habitat.

Table 155. Summary of species critical habitat risk assessments to key physical and biological features – diazinon.

CHAPTER 17

DESIGNATED CRITICAL HABITAT EFFECTS ANALYSIS

MALATHION

TABLE OF CONTENTS

Page

17 MALATHION

17.1 Introduction

The National Marine Fisheries Services (NMFS') critical habitat analysis determines whether the proposed action is likely to destroy or adversely modify critical habitat for Endangered Species Act (ESA)-listed species by examining potential reductions in the conservation value of the essential features of designated critical habitat. "Destruction or adverse modification" means a direct or indirect alteration that appreciably diminishes the value of designated critical habitat for the conservation of an ESA-listed species. Such alterations may include, but are not limited to, those that alter the physical or biological features (PBFs) essential to the conservation of a species or that preclude or significantly delay development of such features (50 C.F.R. §402.02).

In this section, NMFS evaluates the potential consequences to designated critical habitat from exposure to the stressors of the proposed action. A diagram of our analysis framework is shown in ***Figure 1***. It is similar in structure to the jeopardy analysis, but focuses on whether the proposed action is likely to destroy or adversely modify designated critical habitat for listed species. NMFS reviews the status of designated and proposed critical habitat affected by the proposed action separate from species effects by examining the condition and trends of the designated essential physical or biological features (PBFs) of critical habitat throughout the action area. We first determine whether critical habitat is likely to be exposed to the stressors of the proposed action (exposure profile). To conduct this analysis, we relied on R-plots showing expected pesticide concentrations in the species' designated critical habitat. If we find that critical habitat is likely to be exposed, we determined the relevant PBFs for each species' designated critical habitat that would be at risk from this proposed action and assess the consequences of that exposure on the quality, quantity, or availability of those PBFs (response profile) (Appendix C). We relied heavily on EPA provided Crop Land Data Layers of crop uses and conducted an overlap of critical habitat analysis to determine exposure potential to designated critical habitat.

In all of the critical habitat designations that are exposed to the stressors of this action, water quality and forage (prey availability) are key attributes that are either designated as PBFs of the critical habitat, or are relevant to the PBFs. Water quality encompasses a range of typically measured parameters, including dissolved oxygen, temperature, turbidity, and presence of contaminants. Here, we use the presence of chemical contaminants as an indicator of degraded water quality. The proposed action would degrade water quality by introducing chlorpyrifos, diazinon, malathion, and other associated chemicals into designated critical habitats. Therefore, we use the pesticide concentrations likely to adversely affect listed species or prey (e.g. invertebrates and juvenile fish) as measures of degraded water quality. We also note that the PBF's for most of the critical habitats at issue include availability and quality of prey. The three a.i.s are expected to affect prey at concentrations within the range predicted to occur in most freshwater and estuarine habitats by exposure models. This analysis is conducted by comparing toxicity information (e.g., aquatic invertebrate LC_{50} values) provided in EPA's "Effects Characterization" in their BE, with expected pesticide concentrations derived from R-plots using data from EPA's MagTool.

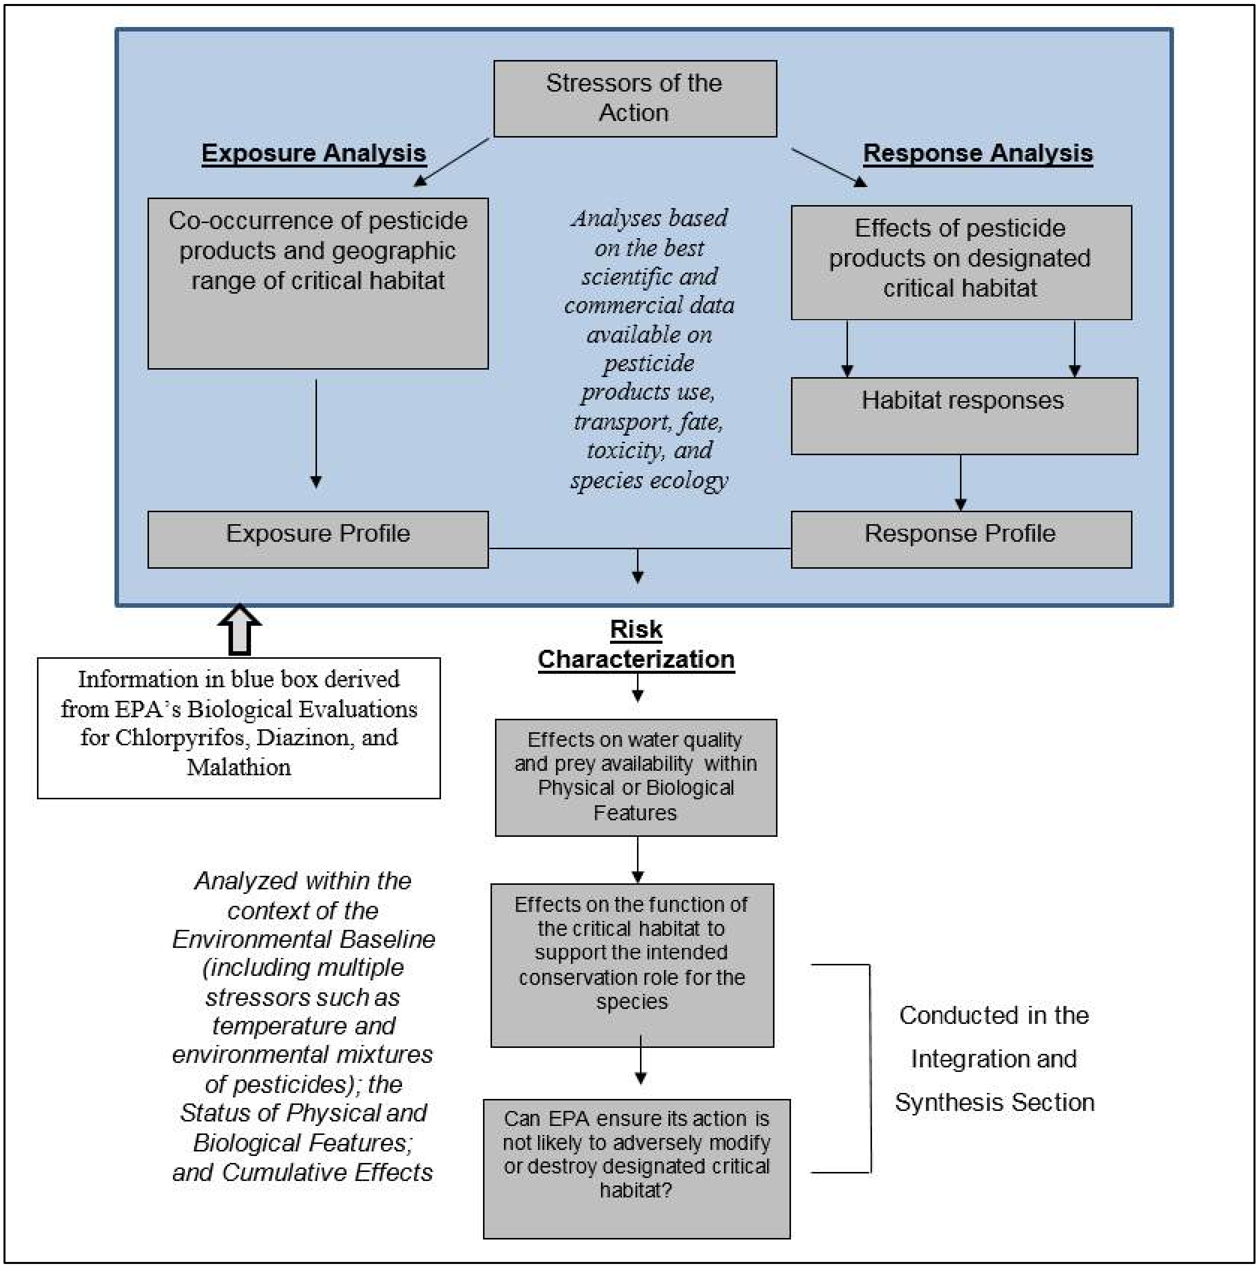

Figure 1. Assessment Framework for Designated Critical Habitat

We translated each PBF into a risk hypothesis to assess potential impacts on designated critical habitat. The analysis of risk hypotheses is based on: 1) the likely concentrations of the three pesticides that would be observed in critical habitat; and 2) the response of PBFs to those anticipated concentrations.

The action area for this Opinion encompasses all designated critical habitat for listed species within the continental U.S., Hawaii, Alaska, and U.S. Protectorates. These species include Pacific salmonids in Washington, Oregon, California and Idaho. As the species of salmonids addressed in this Opinion have similar life history characteristics, they share many of the same PBFs. These PBFs include sites that support one or more life stages and contain physical or biological features essential to the conservation of the Evolutionarily Significant Unit (ESU)/Distinct Population Segment (DPS). PBFs include freshwater spawning sites, freshwater rearing sites, freshwater migration corridors, estuarine areas, nearshore marine areas, and offshore marine areas. Other species include two Puget Sound rockfish species, eulachon, two sturgeon species, two species of corals, black abalone, several species of sea turtles, Southern Resident Killer Whale, two pinniped species, Johnson's seagrass, and Smalltooth sawfish. For each of these species we determined the relevant PBFs that would be affected by the proposed action. Descriptions of species' designated critical habitats and associated PBFs are provided in Appendix C.

Water quality and prey availability in freshwater and estuarine areas may be susceptible to pesticide effects where critical habitat overlaps with or is adjacent to use sites. Effects to water quality and prey availability will be evaluated to determine the likelihood of reducing the quality of freshwater, estuarine, and nearshore marine areas. Given the use and environmental fate profile of the pesticide formulations containing these active ingredients, we do not expect offshore marine areas to be directly affected. Therefore, a risk hypothesis was not developed for this area and further evaluation of this PBF is not warranted.

Sufficient water quality is a necessary attribute of many aquatic PBFs to support the conservation role of designated critical habitat, and water quality unimpaired by toxins is necessary to the PBFs of the critical habitats affected by the stressors of this action. For example, all species of juvenile salmon need clean cold water. Clean and cold water is essential support for producing abundant prey for salmonid growth and development. This is also true for green sturgeon. Eggs and larvae develop in freshwater. Development of early life stages is affectd by water flow and temperature. Juvenile sturgeon rear and feed in fresh and estuarine waters from one to 4 years prior to dispersing into marine waters as subadults. During this time, their growth and development relies on adequate water quality to support abundant prey production. Water quality is clearly degraded when pesticides and other stressors of the action reach levels in habitat that are sufficient to adversely affect aquatic organisms and reduce individual fitness of exposed ESA-listed species. Impacts to species fitness were evaluated earlier in the document and these impacts are used as indicators of degraded water quality. We evaluate exposure and effect concentrations presented in the Environmental Protection Agency's (EPA's) BEs to determine whether PBFs are impacted.

We also evaluate effects on prey because forage is an essential attribute of many PBFs. Freshwater juvenile rearing and migratory habitats as well as estuarine and nearshore marine areas must provide sufficient forage to support growth and development of the listed species. Reductions in the abundance of prey items can decrease the quality of rearing, migration, and estuarine PBFs, as less available food will support fewer individuals. Reductions in prey can reduce a PBF's potential to support species (juvenile development, growth, maturation, survival), thereby reducing the carrying capacity of critical habitat. We evaluated the toxicity assessment endpoints including prey and fish survival (EC_{50}/LC_{50}) to determine whether expected concentrations of the stressors of the action are sufficient to affect PBFs of species critical habitats.

Designated critical habitat is located within the action area. Many freshwater areas overlap with the allowable uses of the three a.i.'s. The stressors of the action contaminate these habitats via drift and runoff (including from irrigation returns), and to a lesser extent from atmospheric deposition. Once in species habitats, the three active ingredients persist for varying periods of time, depending in part on the chemical, biological, and physical environment of the contaminated aquatic habitats. The most persistent of the three, chlorpyrifos (soil half-life 171 days),[1] may accumulate in soils and contribute to aquatic loading via runoff months later affecting organisms beyond those exposed initially from application events. Expected concentrations of other/inert ingredients and adjuvants added to formulations prior to application remain unknown, and are an identified data gap.

We use the toxicity information provided in the BEs and presented earlier in the Effects Analysis Chapters (Chapters 12, 13, and 14) to evaluate the scientific lines of evidence that support or refute risk hypotheses developed for designated and proposed critical habitats. Freshwater spawning and rearing sites, migration corridors, estuarine areas, and nearshore marine areas within designated critical habitats are likely to be exposed to the stressors of the action over the 15-year registration duration. We estimate expected concentrations and durations of exposure for these habitats based on pesticide use information, surface water monitoring data, EPA modeling estimates, and NMFS modeling estimates.

For each risk hypothesis in ***Table 1*** (also refer to Appendix E for specific risk hypotheses for each species PBFs relevant to this analysis) we qualitatively weigh the evidence to determine whether the PBF attributes of water quality and prey availability are affected for each species designated critical habitat. Water quality is degraded when pesticides and other stressors of the action reach levels in habitat that are sufficient to adversely affect aquatic organisms and reduce individual fitness of exposed ESA-listed species (this was evaluated earlier in the document). We ultimately determine whether the degradation of water quality and reduction in prey availability within freshwater spawning and rearing sites, migration corridors, estuarine areas, and nearshore marine areas will rise to the level expected to reduce the intended conservation role of designated critical habitats. This analysis is conducted by evaluating toxicity information (e.g., aquatic invertebrate LC50 values), as well as by characterizing the likelihood of exposure within the designated critical habitat. Likelihood of exposure for critical habitat considers three factors: 1) percent overlap; 2) chemical persistence, and; 3) number of repeated applications allowed. See Chapter 3 for a description of how these factors are considered to determine the overall likelihood of exposure.

See Chapters 22 – 24 (Integration and Synthesis for Designated Critical Habitat) for the final conclusion of whether EPA's proposed action with end-use products containing chlorpyrifos, diazinon, or malathion are likely to adversely modify or destroy a species' designated or proposed critical habitat.

Table 1. Generalized risk hypotheses for relevant PBF's.

Risk hypothesis for relevant physical or biological features
1. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in freshwater spawning sites.
2. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in freshwater rearing sites.

[1] Diazinon soil half-life is 34 days, malathion soil half-life is 1 day.

3. Exposure to the stressors of the action is sufficient to degrade water quality, and/or reduce prey resources in freshwater migratory corridors.
4. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in estuarine areas.
5. Exposure to the stressors of the action is sufficient to degrade water quality and/or reduce prey resources in nearshore marine areas.

The following sections provide the chemical-specific assessments of risk hypotheses for each designated critical habitats involved in this consultation (defined by the action area).

17.2 Columbia River Chum Salmon (O. keta) Designated Critical Habitat

Table 3. Water quality risk hypothesis; chum salmon, Columbia River ESU designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of malathion-containing products occur within Chum salmon, Columbia River ESU designated critical habitat. Twelve use site categories, totaling more than 245,091 acres (over 8% of acres) are currently present. In addition, proposed labels for malathion allow for mosquito control which can be applied to 100% of the species designated critical habitat. The anticipated malathion levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, malathion and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	High	High	Yes

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Columbia River chum salmon. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We have greater confidence in the risk determinations associated with the freshwater habitats than we do in the estuarine and nearshore habitats. Overall the risk is high and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Table 22. Effects analysis summary table; Chinook, Sacramento River winter-run ESU; designated critical habitat.

	R-plot Derived		**Risk Hypothesis Supported?**
Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	**Yes/No**

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat Sacramento River winter-run Chinook salmon. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Table 24. Water quality risk hypothesis; Chinook, Snake River fall-run ESU; designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of malathion-containing products occur within the designated critical habitat of Chinook, Snake River fall-run. Twelve use site categories, totaling more than 3,440,270 acres (over 42% of acres) are currently present. In addition, proposed labels for malathion allow for mosquito control which can be applied to 100% of the species designated critical habitat. The anticipated malathion levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, malathion and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of malathion-containing products occur within the designated critical habitat of Coho, SONC ESU. Eleven use site categories, totaling more than 1,037,089 acres (over eight percent of acres) are currently present. In addition, proposed labels for malathion allow for mosquito control which can be applied to 100% of the species designated critical habitat. The anticipated malathion levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, malathion and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.		
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.		
Risk	**Confidence**	
High	**High**	

Table 46. Effects analysis summary table; Coho, SONC ESU; designated critical habitat.

	R-plot Derived		**Risk Hypothesis Supported? Yes/No**
Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Southern Oregon Northern California coho salmon. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Table 71. Water quality risk hypothesis; Steelhead, Northern California DPS; designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of malathion-containing products occur within the designated critical habitat of Steelhead, Northern California DPS. Ten use site categories, totaling more than 413,593 acres (over 9% of acres) are currently present. In addition, proposed labels for malathion allow for mosquito control which can be applied to 100% of the species designated critical habitat. The anticipated malathion levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, malathion and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.		
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.

Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	High	High	Yes

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat Northern California steelhead. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Risk Hypothesis: Exposure to the stressors of the action is sufficient to reduce prey in freshwater spawning, rearing, migratory corridors, estuarine, and nearshore marine habitats.*			
Risk	**Confidence**	***We have low confidence in EECs associated with marine and estuarine habitats.**	
High	**High**		

Table 95. Water quality risk hypothesis; Steelhead, upper Willamette River DPS; designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of malathion-containing products occur within the designated critical habitat of Steelhead, upper Willamette River DPS. Twelve use site categories, totaling more than 982,770 acres (over 44% of acres) are currently present. In addition, proposed labels for malathion allow for mosquito control which can be applied to 100% of the species designated critical habitat. The anticipated malathion levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation. Additionally, where elevated temperatures occur, malathion and other co-occurring organophosphates will exhibit greater toxicity to fish and invertebrates.		
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.		
Risk	**Confidence**	
High	**High**	

Table 96. Effects analysis summary table; Steelhead, upper Willamette River DPS; designated critical habitat.

	R-plot Derived		**Risk Hypothesis Supported? Yes/No**
Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water	High	High	Yes

quality and/or reductions in prey in freshwater rearing sites.			
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat upper Willamette River steelhead. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in the estuarine and nearshore habitats.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect relavent physical or biological features within estuarine and nearshore habitats of gulf sturgeon. However, we have low confidence in the EECs predicted for the nearshore habitats. Within the nearshore and estuarine portions of their range, we do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Designated Critical Habitat Effects Analysis Summary:

We anticipate a high likelihood that the stressors of the action will negatively affect physical or biological features (PBFs). Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of Atlantic Sturgeon, Chesapeake Bay DPS. The likelihood and magnitude of toxic effects may reduce the overall conservation value of designated critical habitat. We find that the overall risk is high and the confidence associated with that risk is high over the 15-year duration of the action.

Table 122. Water quality risk hypothesis; Atlantic Sturgeon, Carolina DPS; designated critical habitat.

Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of malathion-containing products occur within the designated critical habitat of Atlantic sturgeon, Carolina DPS. Eleven use site categories, totaling more than 541,668 acres (over 15% of acres) are currently present. In addition, proposed labels for malathion allow for mosquito control which can be applied to 100% of the species designated critical habitat. The anticipated malathion levels in designated critical habitat are sufficient to kill fish and aquatic invertebrates, and for the animals that survive, impaired swimming, reduced reproduction, and reduced growth are anticipated. Multiple (*perhaps all*) habitat types will experience levels that degrade water quality. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation.

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect relevant physical or biological features within estuarine and nearshore habitats of yelloweye rockfish. However, we have low confidence in the EECs predicted for the marine nearshore habitats. Within the nearshore and estuarine portions of their range, we do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.	High	Low	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

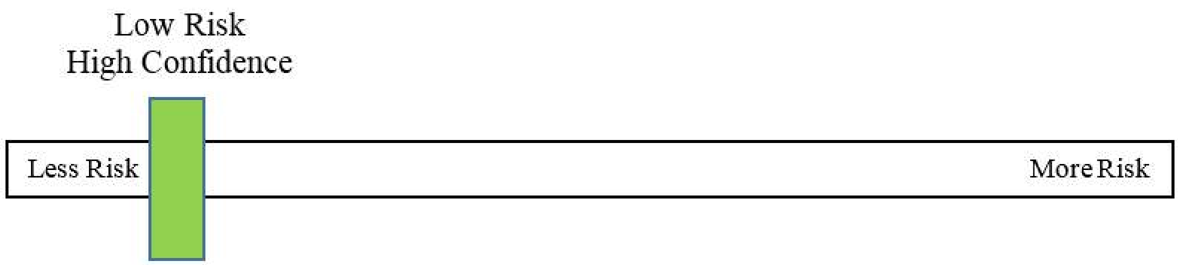
The stressors of the action may negatively affect relaventrelevant physical or biological features within nearshore habitats of the black abalone. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

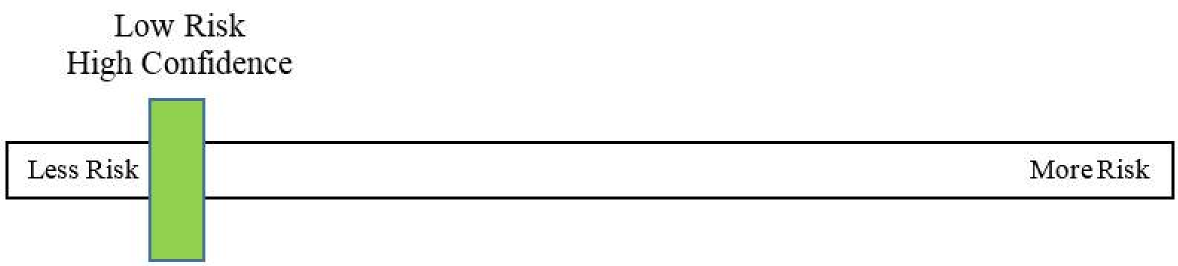
17.42 Staghorn Coral Designated Critical Habitat

There are no physical or biological features identified in Staghorn Coral designated critical habitat that could be affected by the proposed action. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.



17.43 Elkhorn Coral Designated Critical Habitat

There are no physical or biological features identified in Elkhorn Coral designated critical habitat that could be affected by the proposed action. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.



17.44 Green Sea Turtle (North Atlantic DPS) Designated Critical Habitat

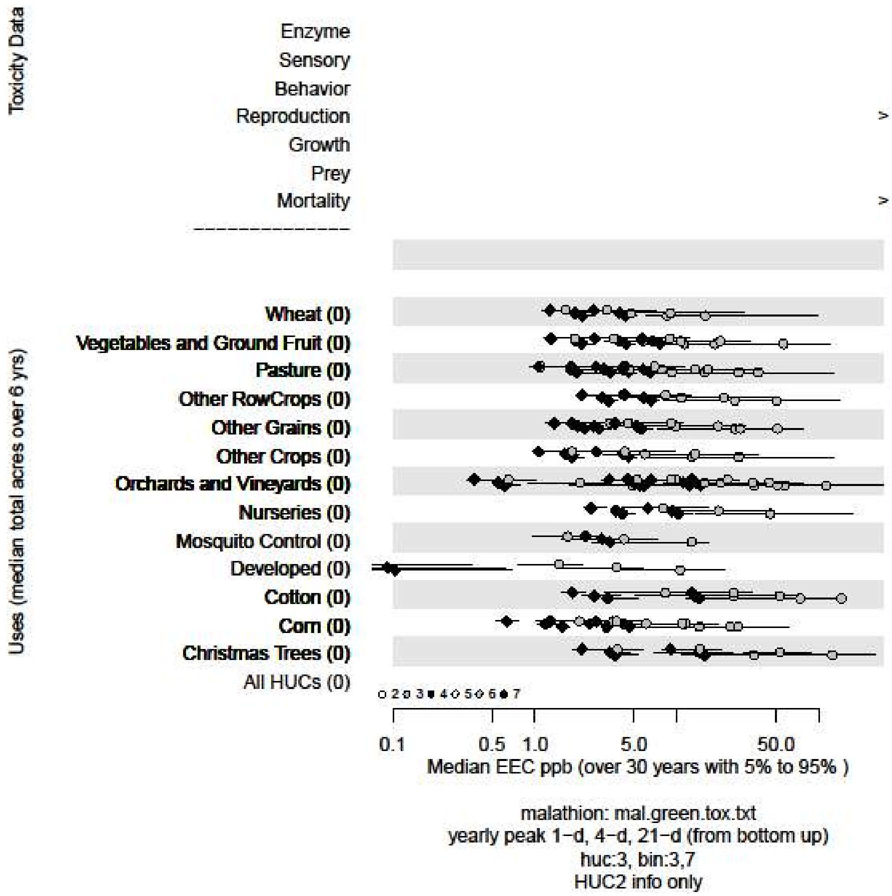


Figure 42. Effects analysis R-plot; Green Sea Turtle, North Atlantic DPS designated critical habitat.

Table 142. Water quality risk hypothesis; Green sea turtle, North Atlantic DPS; designated critical habitat.

Endpoint: Water Quality
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of malathion-containing products may occur within the designated critical habitat of Green sea turtle, North Atlantic DPS. Proposed labels for malathion allow for mosquito control and wide area use, both of which can be applied to 100% of the species designated critical habitat. The anticipated malathion levels in designated critical habitat may be sufficient to cause adverse effects to sea turtles. The likelihood of attaining these concentrations increases with frequency of application, use of the maximum rates, and the proximity to designated critical habitats. Other chemicals within formulations or added to tank mixes increases the extent of water quality degradation.
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.

Risk	Confidence	
High	Low

Designated Critical Habitat Effects Analysis Summary:

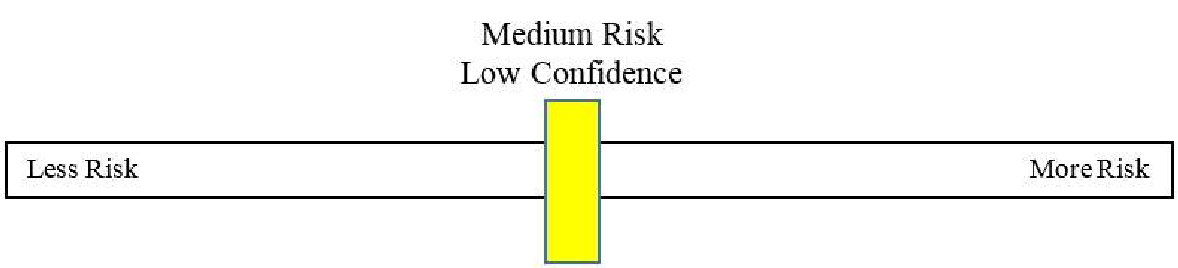
The stressors of the action may negatively affect a relevant physical and biological feature within the nearshore of each of the designated critical habitat areas if the leatherback sea turtle. However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.



17.47 Loggerhead Sea Turtle (NW Atlantic Ocean DPS) Designated Critical Habitat

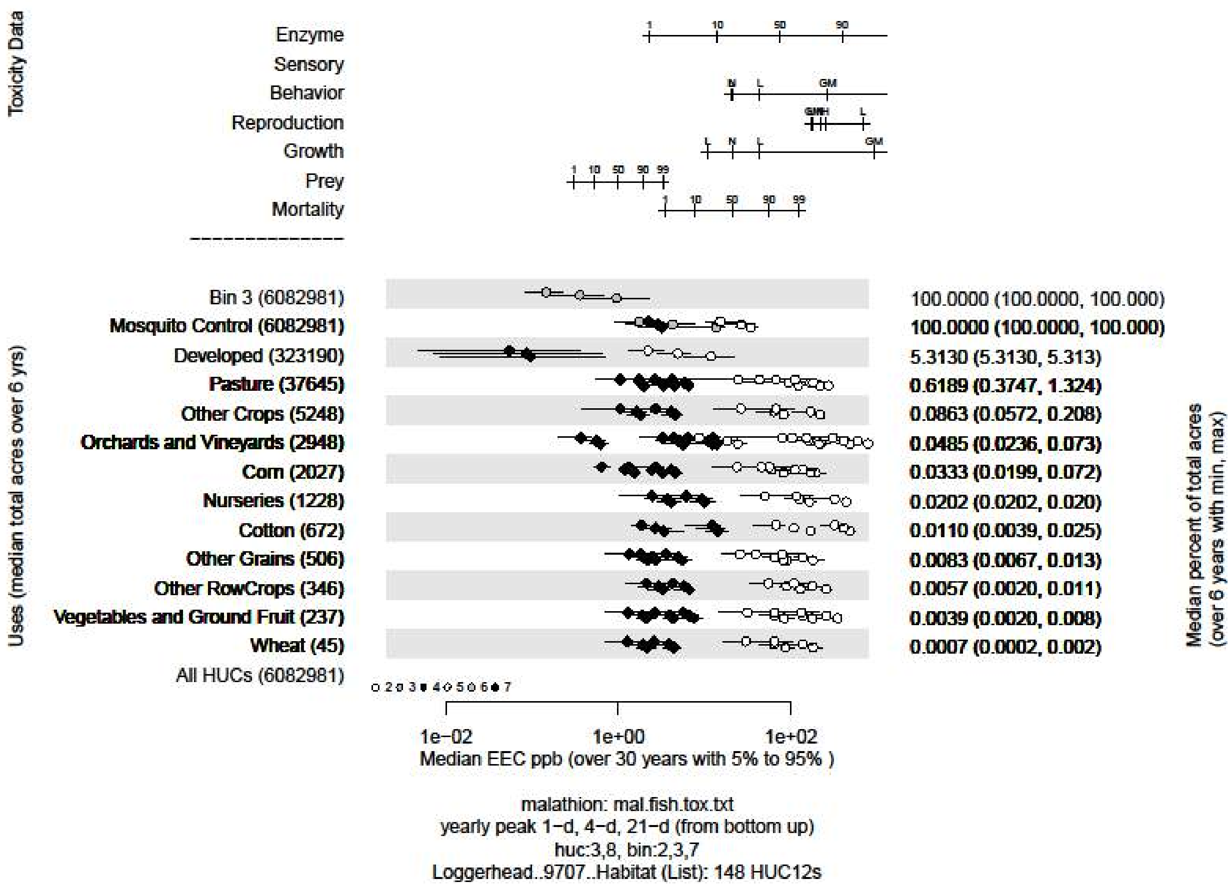


Figure 46. Effects analysis R-plot; Loggerhead sea turtle, NW Atlantic DPS designated critical habitat.

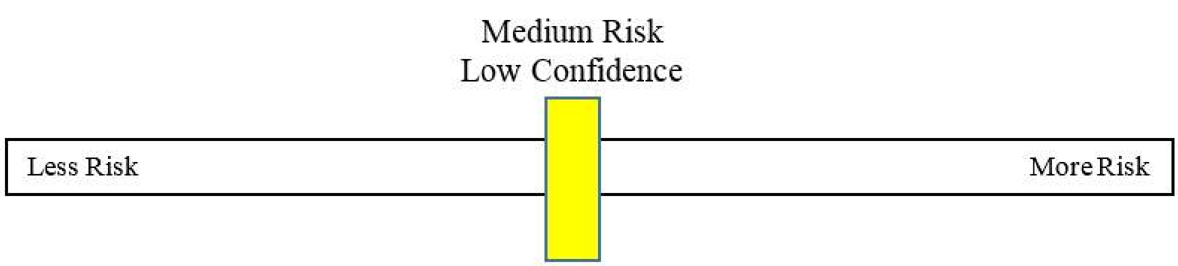
Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	**Yes/No**
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.	High	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of the loggerhead sea turtle. However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.



17.48 Southern Resident Killer Whale Designated Critical Habitat

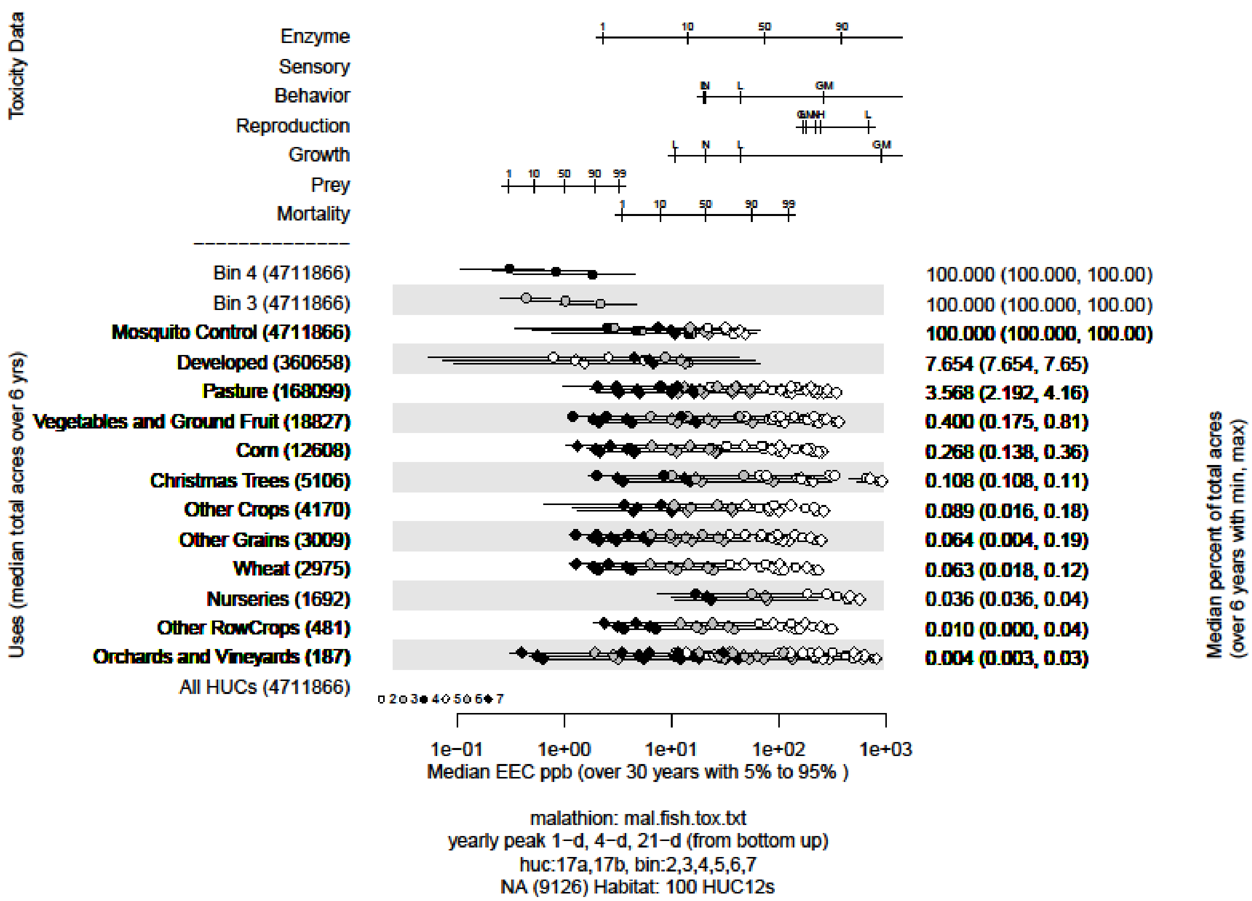


Figure 47. Effects analysis R-plot; Southern Resident Killer Whale designated critical habitat.

Risk Hypothesis: Direct exposure to the stressors of the action within designated critical habitat is sufficient to reduce prey (fish).			
Risk	**Confidence**		
High	**Low**		
Risk Hypothesis: Exposure to the stressors of the action outside of designated critical habitat is sufficient to in-directly reduce prey availability (Chinook salmon).			
Risk	**Confidence**	**Affecting the availability of prey species of sufficient quantity and quality. Jeopardy determinations were made for all ESU's of Chinook salmon with regard to the proposed action.**	
High	**High**		

Table 151. Water quality risk hypothesis; Killer whale, Southern resident DPS; designated critical habitat.

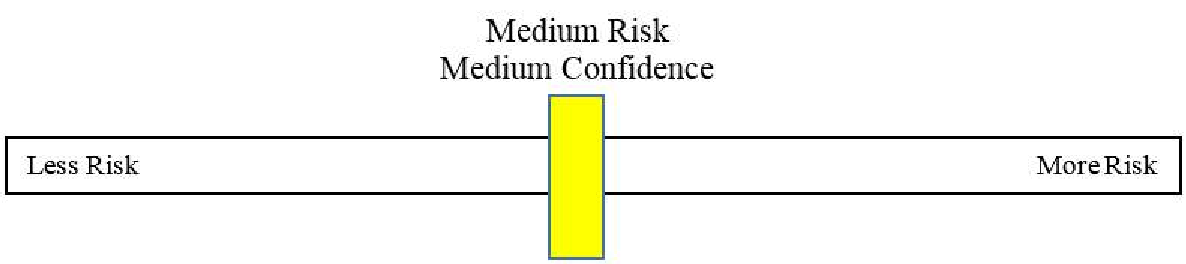
Endpoint: Water Quality		
Compromised water quality occurs when anticipated concentrations of the stressors of the action achieve toxic levels in designated critical habitat. Authorized uses of malathion-containing products occur in proximity to the designated critical habitat of Killer whale, Southern resident DPS. Twelve use site categories, totaling more than 577,812 acres (over 13% of acres) are currently present. In addition, proposed labels for malathion allow for mosquito control which can be applied to 100% of the species designated critical habitat. The anticipated malathion levels in designated critical habitat are not sufficient to cause adverse effects to killer whales.		
Risk Hypothesis: Exposure to the stressors of the action is sufficient to degrade water quality.		
Risk	**Confidence**	
Low	**High**	

Table 152. Effects analysis summary table; Killer whale, Southern resident DPS; designated critical habitat.

	R-plot Derived		Risk Hypothesis Supported? Yes/No
Designated Critical Habitat; Risk Hypotheses	**Risk**	**Confidence**	
Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.	Low	High	No
Exposure to the stressors of the action outside of designated critical habitat is sufficient to in-directly reduce the conservation value via reductions in prey availability (Chinook salmon).	High	High	Yes
Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.	Low	High	No

Designated Critical Habitat Effects Analysis Summary:

We do not anticipate stressors of the action will directly affect physical or biological features (PBFs). Reductions in suitable prey (within designated critical habitat) and degradation of water quality are unlikely throughout designated critical habitat of Southern Resident Killer Whale. However, indirectly, prey species (salmon) will be adversely affected by exposures anticipated in their freshwater habitats. The likelihood and magnitude of toxic effects will reduce the overall conservation value of designated critical habitat by reducing the availability of these important prey. We find that the overall risk is medium and the confidence associated with that risk is medium over the 15-year duration of the action.



17.49 Stellar Sea Lion (Western DPS) Designated Critical Habitat

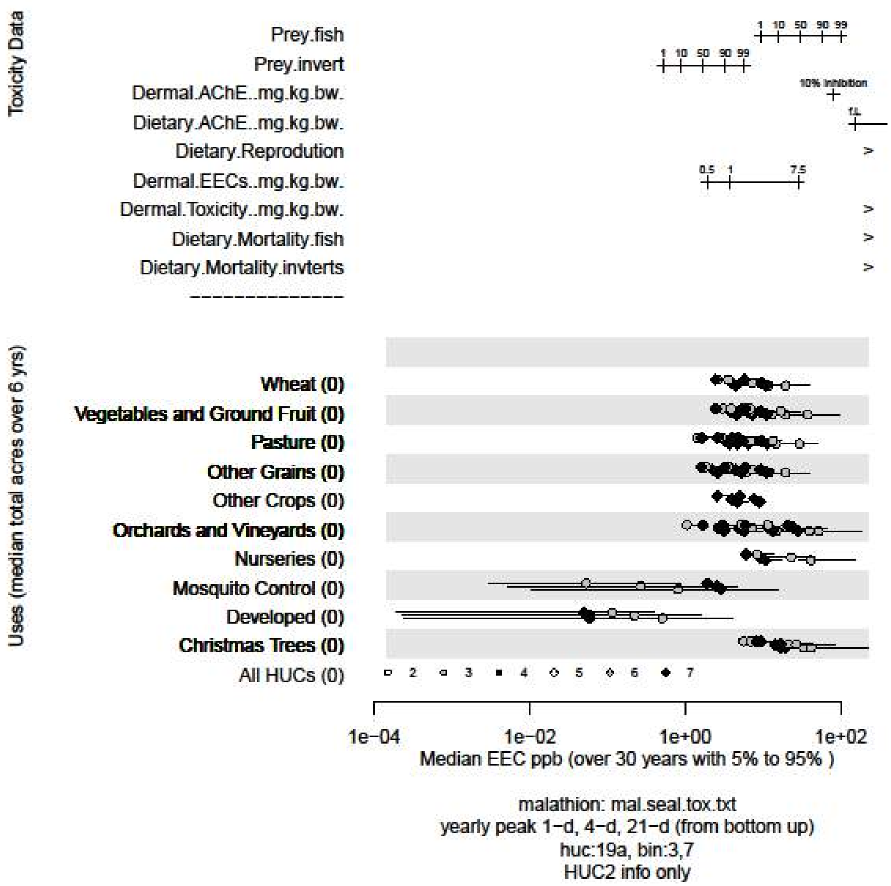


Figure 48. Effects analysis R-plot; Steller sea lion, Western DPS designated critical habitat.

Table 153. Effects analysis summary table; Steller sea lion, Western DPS; designated critical habitat.

Designated Critical Habitat; Risk Hypotheses	R-plot Derived		Risk Hypothesis Supported? Yes/No
	Risk	Confidence	
Exposure to the stressors of the action is sufficient to cause reductions in prey.	Medium	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of the Steller sealion. However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

17.50 Hawaiin Monk Seal Designated Critical Habitat

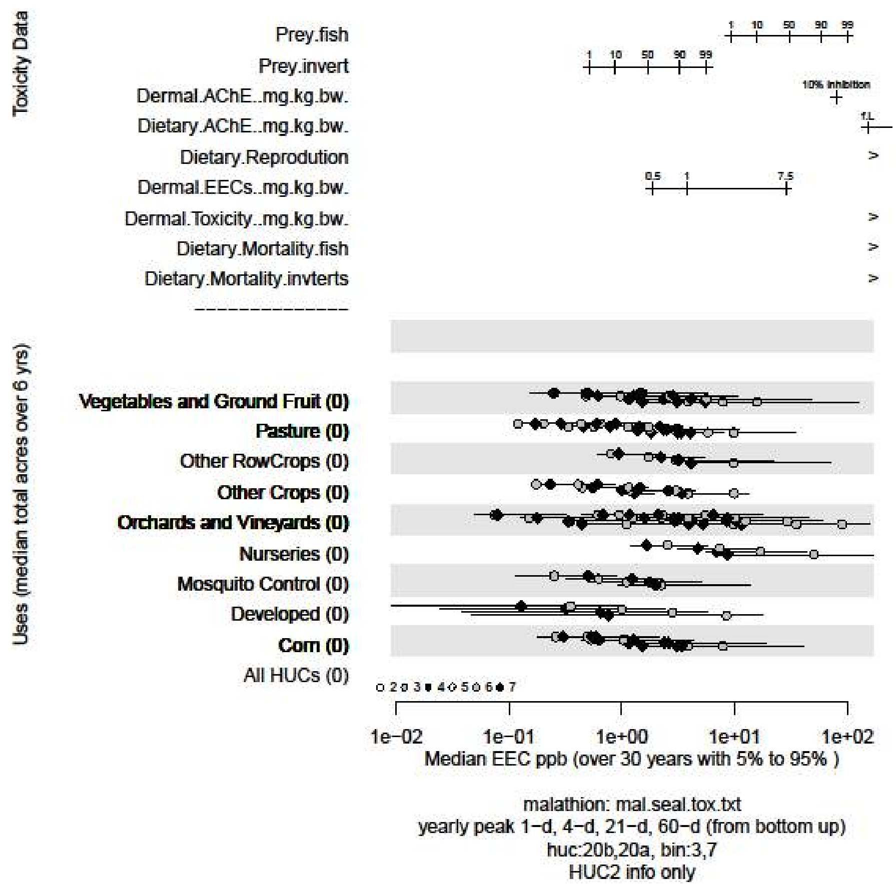

Figure 49. Effects analysis R-plot; Hawaiian Monk Seal designated critical habitat.

Table 154. Effects analysis summary table; Hawaiian Monk Seal designated critical habitat.

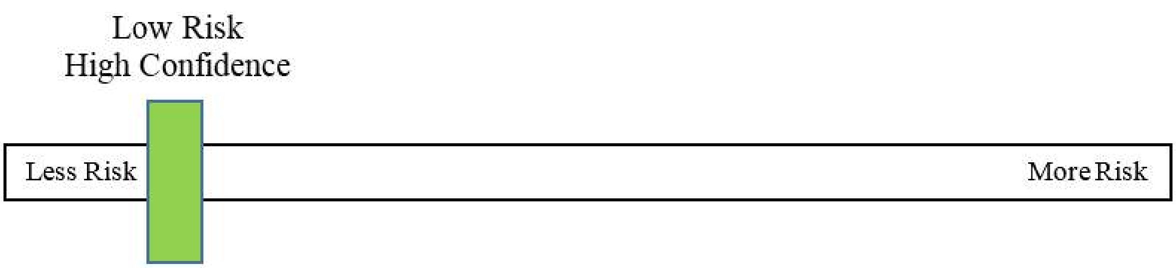
Designated Critical Habitat; Risk Hypotheses	R-plot Derived		Risk Hypothesis Supported? Yes/No
	Risk	**Confidence**	
Exposure to the stressors of the action is sufficient to cause reductions in prey.	Medium	Low	Yes

Designated Critical Habitat Effects Analysis Summary:

The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of the Hawaiian monk seal. However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

17.51 Johnson's Seagrass Designated Critical Habitat

Water quality is a physical or biological features identified in Johnson's seagrass designated critical habitat. However, we do not anticipate exposures from the stressors of the action to be sufficient to reduce conservation values of this PBF. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.



17.52 Summary of the Effects of the Action on Physical or Biological Features:

We conclude that the available information on exposure and response of aquatic habitats to the stressors of the action supports risk hypotheses for many of the species. ***Table 155*** summarizes for malathion and for the species habitats where risk hypotheses are supported. We expect water quality and prey abundance to be reduced in spawning, rearing, migratory, estuarine, or nearshore marine habitats for many of the species' designated critical habitats. Next, within the Integration and Synthesis for Designated Critical Habitat section, we evaluate whether these adverse changes to PBFs affect the conservation value of designated critical habitat.

Table 155. Summary of species critical habitat risk assessments to key physical and biological features – malathion.

Species Designated Critical Habitat	Water Quality and/or Prey Risk Hypotheses Supported (Malathion)
Chum salmon , Columbia River ESU	Yes
Chum salmon, Hood Canal summer-run ESU	Yes
Chinook salmon, California coastal ESU	Yes
Chinook salmon, Central Valley spring-run ESU	Yes
Chinook salmon, Lower Columbia River ESU	Yes
Chinook salmon, Puget Sound ESU	Yes

Green sea turtle, North Atlantic DPS	No
Hawksbill sea turtle	No
Leatherback sea turtle	No

Loggerhead sea turtle, Northwest Atlantic Ocean DPS	No
Killer whale, Southern Resident DPS	Yes
Steller sea lion, Western	No
Hawaiian monk seal	No
Johnson’s seagrass	No

CHAPTER 18

CUMULATIVE EFFECTS

TABLE OF CONTENTS

Page

18 CUMULATIVE EFFECTS

18.1 Introduction

Cumulative effects include the effects of future state, tribal, local, or private actions that are reasonably certain to occur in the action area considered by this Opinion. Future federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the Endangered Species Act (ESA).

During this consultation, the National Marine Fisheries Service (NMFS) searched for information on future state, tribal, local, or private actions that were reasonably certain to occur in the action area. NMFS conducted electronic searches of business journals, trade journals, and newspapers using Google and other electronic search engines. Those searches produced reports on projected population growth, commercial and industrial growth, and global warming. Trends described below highlight the effects of population growth on existing populations and habitats for all 28 ESUs/DPSs. Changes in the near-term (five-years; 2018) are more likely to occur than longer-term projects (10-years; 2023). Projections are based upon recognized organizations producing best available information and reasonable rough-trend estimates of change stemming from these data. NMFS analysis provides a snapshot of the effects from these future trends on listed ESUs.

Cumulative effects include the effects of future state, tribal, local, or private actions that are reasonably certain to occur in the action area considered by this Opinion. Future federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the ESA.

The information from the Cumulative Effects section is treated as a “risk modifier” in the Integration and Synthesis section (Chapters 19-24). Factors which have the potential to “modify” the risk are those which are able to interact with the effects of the action. For example, elevated temperatures have been demonstrated to increase the toxicity of certain pesticide mixtures to juvenile coho salmon (Laetz et al. 2014). While many of the factors described in this section have the potential to modify the action, and were thus considered, two of the factors were consistently found to have a high potential to modify the risk. The two factors are: 1) elevated temperatures in marine and freshwater habitats, and 2) hydrologic effects in freshwater habitats. We therefore developed two key questions to guide our synthesis of the information within the Cumulative Effects section:

1. Will future temperatures impair species aquatic habitats?
2. Will future hydrologic flows impair freshwater species habitats?

We divide the species into three groupings: 1) species which are anadromous or that have life history stages within freshwater habitats; 2) marine fish and abalone; and 3) marine mammals, sea turtles, corals, and seagrass. For the first grouping, we used best available information to answer the two questions. For the second and third groupings, we used best available science to answer the first question only as we do not anticipated altered hydrologic flows (due to changes in rainfall and snowmelt) to affect marine environments.

In order to assess potential changes in future aquatic temperatures and future hydrological flows, NMFS searched for information on future state, tribal, local, or private actions that were reasonably certain to occur in the action area. NMFS conducted electronic searches of business journals, trade journals, and newspapers using Google and other electronic search engines. Those searches produced reports on projected population growth, commercial and industrial growth, and climate change (see summaries below). Projections are based upon recognized organizations producing best available information and reasonable rough-trend estimates of change stemming from these data. NMFS analysis provides a snapshot of the effects from these future trends on listed Evolutionarily Significant Units (ESUs)/ Distinct Population Segments (DPS).

In general, NMFS found:

For freshwater and/or anadromous species. Future elevated temperatures and altered hydrologic conditions are likely to affect all freshwater and/or anadromous species. Two species are exceptions to this general rule since NMFS' jurisdiction of both Atlantic salmon and Gulf sturgeon is limited to the marine environment where temperature and hydrologic effects are less likely.

For marine fish and abalone. Neither future elevated temperatures, nor altered hydrologic conditions are likely to affect marine fish and abalone.

For marine mammals, sea turtles, corals, and seagrass. Future elevated temperatures or hydrologic alterations (from rainfall or changes in snowmelt) are not likely to affect these species.

Within the Integration and Synthesis section (Chapters 19-24), we characterize the overall magnitude of influence of the Cumulative Effect as either "low" or "high". This characterization includes directionality (i.e. positive influence or negative influence) as well as confidence. The magnitude, directionality, and confidence of the influence are determined primarily by answers provided to the two key questions outlined above. Confidence is determined by assessing the amount of evidence provided, as well as by further considering the species-specific implications of the two main factors.

18.2 U.S. Population Growth

The U.S. population is growing at a net rate of one person every 14 seconds. Regional data from the U.S. Census Bureau show the South has the highest population at 120 million, followed by the West at 80 million. The Midwest and the Northeast populations are at 75 and 60 million (respectively). ***Figure 1*** depicts the annual rate of growth from the year 2000 to 2015 for each of these regions. Currently the population of the U.S. stands at over 325,032,400 and counting (https://www.census.gov/popclock/). By 2060, the U.S. population is projected to increase to 417 million, reaching 400 million in 2051.

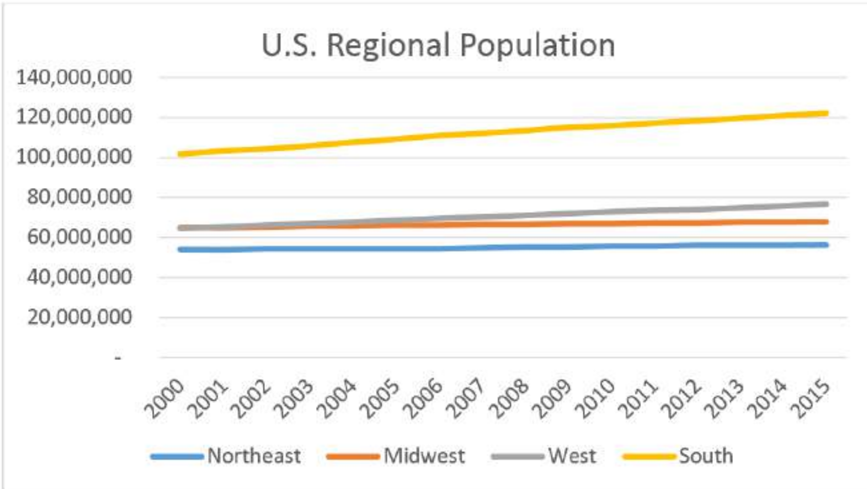

Figure 1. U.S. Population increase by region 2000-2015 (U.S. Census Bureau)

Figure 1 shows the trend in growth over a sixteen-year span. Growth rate in the south was greatest, followed by the West region. The Midwest and Northeast growth rates remained mostly flat taken as a region as a whole. Of particular concern to NMFS' listed species is the population growth within coastal counties. Coastline counties of the U.S., located along the country's saltwater edges, account for just 255 of the nation's 3,142 counties yet contain 29% of its population, 5 of its 10 most populous cities, and 7 of 10 of its most populous counties (Mackun et al, 2011). Between 1960 and 2008, the percentage increase in population along the coastal counties (84%) was greater than that of non-coastal counties (64%). Among the coastal regions, the percentage increase in population in the Gulf of Mexico (150%) and the Pacific (110%) far outpaced the gains for the Atlantic region (56%). Growth in the coastal counties are expected to continue to outpace non-coastal counties.

Population growth will require greater and greater demand on resources, greater demand for food and water, and greater demand for energy. The increase in demand for these essential items are likely to extend pressures on many threatened and endangered species populations and their designated critical habitats. As many cities border coastal or riverine systems, diffuse and extensive growth will increase overall volume of contaminant loading from wastewater treatment plants and sediments from expanding urban and suburban development into riverine, estuarine, and marine habitats. Urban runoff from expanding impervious surfaces and existing and additional roadways may also contain oil, heavy metals, polycyclic aromatic hydrocarbons, and other chemical pollutants and flow into state surface waters. Inputs of these point and non-point pollution sources into numerous rivers and their tributaries will affect water quality in available spawning and rearing habitat for salmon. Based on the increase in human population growth, we expect an associated increase in the number of National Pollution Discharge Elimination System (NPDES) permits issued and the potential listing of more 303(d) waters with high pollutant concentrations in state surface waters. Continued growth into forested and other natural areas will continue the cycle of altering landscapes to the detriment of species habitat. Altered landscapes, such as the loss of riparian vegetation along rivers and increases in impervious surfaces, adversely affect the delivery of sediment and gravel and significantly alter stream hydrology and water quality.

A rise in the population would necessitate a rise in agricultural output, and the potential conversion of forested and other natural lands to agriculture. As most of the coastal states have large tracts of irrigated agriculture, this rise in agricultural output is anticipated to affect coastal areas and aquatic species. Impacts from heightened agricultural production will likely result in two negative impacts on listed species. The first impact may come from a needed reliance and greater use and application of pesticide, fertilizers, and herbicides and their increased concentrations and entry into freshwater systems. Toxics and other pollutants from agricultural runoff may further degrade habitats supporting listed species. Second, increased output and water diversions for agriculture may also place greater demands upon limited water resources. Water diversions will reduce flow rates and alter habitat throughout freshwater systems. Reductions in flows could mean higher water temperatures, and as water is drawn off, contaminants will become more concentrated in these systems, exacerbating toxicity issues in habitats for protected species.

The above issues are likely to pose continuous unquantifiable negative effects on listed species addressed in this Opinion, particularly freshwater and anadromous species, and those species adapted to and requiring nearshore and estuarine habitats. Each activity has negative effects on water quality. They include increases in sedimentation, increased point and non-point pollution discharges, decreased infiltration of rainwater (leading to decreases in shallow groundwater recharge, decreases in hyporrheic flow (e.g., water that spreads laterally beneath river gravels outside the channel where surface flows occur), and decreases in summer base flows). For example, EPA recently released draft *National Rivers and Streams Assessment 2008-2009 – Collaborative Survey* (EPA 2013) revealed only 41.9% of rivers and streams in the west were in good overall biological condition. Biological condition is the most comprehensive indicator of water body health. When the biology of a stream is healthy, the chemical and physical components of the stream are also typically in good condition. The EPA assessment indicated that the overall health of the rivers and streams has declined when compared to past surveys. Nationally, the amount of stream length in good quality for macroinvertebrate condition dropped from 27.4% in 2004 to 20.5%.

18.3 Climate Change

Climate change is an important factor in the long-term survival and recovery of ESA listed species. Salmon and steelhead, sturgeon and eulachon throughout their respective range are likely to be affected by a changing climate both directly and indirectly with increasing water temperatures and reduced instream summer flows. Several studies have revealed that climate change has the potential to affect ecosystems in nearly all tributaries throughout the Northwest and California where abundant cold water flows are essential for the conservation of species habitats (Battin et al. 2007; IPCC 2013; McClure et al. 2013; Crozier and Dechant 2014). While the intensity of effects will vary by region (ISAB 2007), climate change is generally expected to alter aquatic habitat (water yield, peak flows, and stream temperature). As climate change alters the structure and distribution of rainfall, snowpack, and glaciations, each factor will in turn alter riverine hydrographs. Given the increasing certainty that climate change is occurring and is accelerating (Battin et al. 2007), NMFS anticipates salmonid, sturgeon, and eulachon habitats will be affected. Climate and hydrology models project significant reductions in both total snow pack and low-elevation snow pack in the Pacific Northwest over the next 50 years (Mote and Salathe 2009) – changes that will shrink the extent of the snowmelt-dominated habitat available to theses threatened and endangered species. Such changes may restrict our ability to conserve diverse life histories for many of these species.

Hydrologic changes in streamflow may harm the spawning and migration of sturgeon, eulachon, salmon and trout species. Continued warming of stream and lake temperatures may also affect the health of and the extent of suitable habitat for many other aquatic species. Salmonids and other species that currently live in conditions near the upper range of their thermal tolerance are particularly vulnerable to higher stream temperatures, increasing susceptibility to disease and rates of mortality. Upstream migration for thermally-stressed species may be impeded by changes in channel structure from altered low-flow regimes. Reduced glacier area and *volume* over the long-term, which is projected for the future in the North Cascades, may challenge Pacific salmonids in those streams in which glacier melt comprises a significant proportion of streamflow (Dalton, Mote and Snover, 2013).

Altered ocean conditions projected with climate change include sea-level rise and ocean acidification (IPCC 2013). The Intergovernmental Panel on Climate Change (IPCC) reports with virtual certainty that the upper ocean (0-700m) warmed from 1971 to 2010. On the global scale, the ocean warming is largest near the surface, and the upper 75m warmed by 0.11 [0.09-0.13] °C per decade over this 40 year period.

Since the early 1970s, glacier melt and ocean thermal expansion from warming together explain much of the observed global sea-level rise.

The atmospheric concentrations of carbon dioxide, methane, and nitrous oxide have increased to levels unprecedented in at least 800,000 years and these levels are projected to increase further. Carbon dioxide concentrations have increased by 40% since pre-industrial times, primarily from fossil fuel emissions and secondarily from net land use change emissions. The ocean has absorbed about 30% of the emitted carbon dioxide, causing the ocean to acidify (IPCC 2013). The pH of the ocean surface water has decreased by 0.1 since the beginning of the industrial era, corresponding to a 26% increase in hydrogen ion concentration. The IPCC (2013) projects the global ocean will continue to warm during the 21st century. Heat will penetrate from the surface to the deep ocean and affect circulation. Best estimates of ocean warming in the top one hundred meters are as high as 2.0 °C (RCP8.5), and up to 0.6 °C at a depth of 1000 meters by the end of the century.

Projected increases in ocean warming and ocean acidification may have severe effects on corals and other marine invertebrates. Warmer water temperatures can result in coral bleaching Heron et al, 2016). At warmer temperatures, corals expel the symbiotic algae (zooxanthellae) living in their tissues causing the coral to turn completely white. Corals can survive bleaching events, but they are under more stress and are subject to mortality. The U.S. lost half its coral reefs in the Caribbean in 2005. Comparison of satellite data from the previous 20 years confirmed that thermal stress from the 2005 event was greater than the previous 20 years combined (NOAA NOS). Climate models project the percentage of reef locations exposed to bleaching-level thermal stress events to increase. By 2050, more than 98% of reefs are expected to be exposed to bleaching-level thermal stress (Heron et al 2016).

The oceans have absorbed much of the carbon dioxide (CO_2) released from the burning of fossil fuels, and other land-use emissions, resulting in chemical reactions that lower pH (Tans, 2009). This has caused an increase in hydrogen ion (acidity) of about 30% since the start of the industrial age. A process known as “ocean acidification.” A growing number of studies have demonstrated adverse impacts on marine organisms, including: 1) the rate at which reef-building corals produce their skeletons decreases, 2) the ability of marine algae and free-swimming zooplankton to maintain protective shells is reduced, and 3) the survival of larval marine species including commercial fish and shellfish is reduced (e.g. Feely et al, 2009, Kleypas et al. 2009, Cooley et al. 2009, Cohen and Holcomb 2009).

Calcium carbonate, or calcite ($CaCO_3$), and other important carbonate minerals are essential for many marine invertebrates. Benthic calcifiers, such as corals and mollusks are listed species that require uptake of calcite minerals for growth and survival. A variety of evidence indicates that their calcification rates will decrease (see citations above). As the ocean pH continues to dip (i.e. acidify) with the uptake of more CO_2, the saturation states of carbonate minerals calcite, aragonite, and magnesium calcite will lower. Calcification rate will decrease, and carbonate dissolution rates will increase. This will leave less of these minerals available and add stress to organisms that must form supporting skeletal structures for their growth and survival (Kleypas et al. 2006).

CHAPTER 19

INTEGRATION AND SYNTHESIS FOR LISTED SPECIES

CHLORPYRIFOS

TABLE OF CONTENTS

19 CHLORPYRIFOS

19.1 Introduction

The integration and synthesis section is the final step in our assessment of the risk posed to species and critical habitat as a result of implementing the proposed action. In this section, we add the effects of the action (Chapter 12) to the environmental baseline (Chapter 10) and the cumulative effects (Chapter 18) to formulate the agency's biological opinion as to whether the proposed action is likely to: (1) reduce appreciably the likelihood of both the survival and recovery of Endangered Species Act (ESA)-listed species in the wild by reducing its numbers, reproduction, or distribution; or (2) appreciably diminish the value of designated critical habitat for the conservation of an ESA-listed species. These assessments are made in full consideration of the Status of the Species (Chapter 9).

We treat the information from the status of the species, environmental baseline, and cumulative effects, as "risk modifiers," in that the effects described in the effects analysis section may be modified by the condition of the species; the condition of environmental baseline, and the anticipated cumulative effects. The key questions addressed include:

1) Status of the Species:
    - Are abundance, spatial distribution, and productivity trends increasing, decreasing or stable?
    - Is the species listed as threatened, or as endangered?
    - Have recovery goals been met, or are they on a sustained positive trajectory toward recovery?
2) Environmental Baseline:
    - Are freshwater temperatures elevated?
    - Are pesticide mixtures present, or anticipated based on current land use?
3) Cumulative Effects:
    - Will future temperatures impair species aquatic habitats?
    - Will future hydrologic flows impair freshwater species habitats?

Once each of the above sections is evaluated i.e., questions answered, the effects of the action and the risk modifiers are depicted graphically on a "scorecard." First, we assign a magnitude of influence (low or high) indicated graphically with one of two lengths of arrows. The shorter of the two arrows indicates a low magnitude, while the longer of the two arrows indicates a high magnitude as a risk modifier. The direction an arrow is pointed indicates the directionality of the risk modifier. For example, an environmental baseline arrow pointing towards more risk may indicate that environmental mixtures and elevated temperatures occur in the environmental baseline, which further stresses the species in question. We also assign a level of confidence in our selection of the small and large magnitude, indicated by a bold arrow (high confidence) or an un-bolded arrow (low confidence). The final arrow representing the influence on risk is graphically depicted on each species' scorecard.

Figure 1. Example of arrows to represent direction, magnitude, and confidence of risk modifiers

Conclusion Section:

With full consideration of the status of the species and the designated critical habitat, we construct a description of the effects of the action within the action area on populations or subpopulations, when added to the environmental baseline and the cumulative effects, to determine whether the action could reasonably be expected to:

- Reduce appreciably the likelihood of survival and recovery of ESA-listed species in the wild by reducing its numbers, reproduction, or distribution, and state our conclusion as to whether the action is likely to jeopardize the continued existence of such species; or
- Appreciably diminish the value of designated critical habitat for the conservation of an ESA-listed species, and state our conclusion as to whether the action is likely to destroy or adversely modify designated critical habitat.

A scorecard is generated for each species and designated critical habitat. The effects of the proposed action is considered, as modified by the magnitude and confidence of the three arrows. Next, a no-jeopardy or jeopardy bar is placed on the risk bar i.e., the colored bar beginning with green (less risk) to red (more risk) (***Figure 2***).

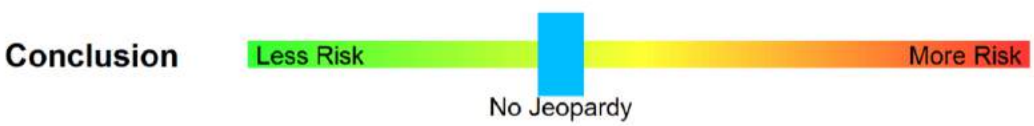

Figure 2: Example conclusion graphic

19.2 Species Scorecards

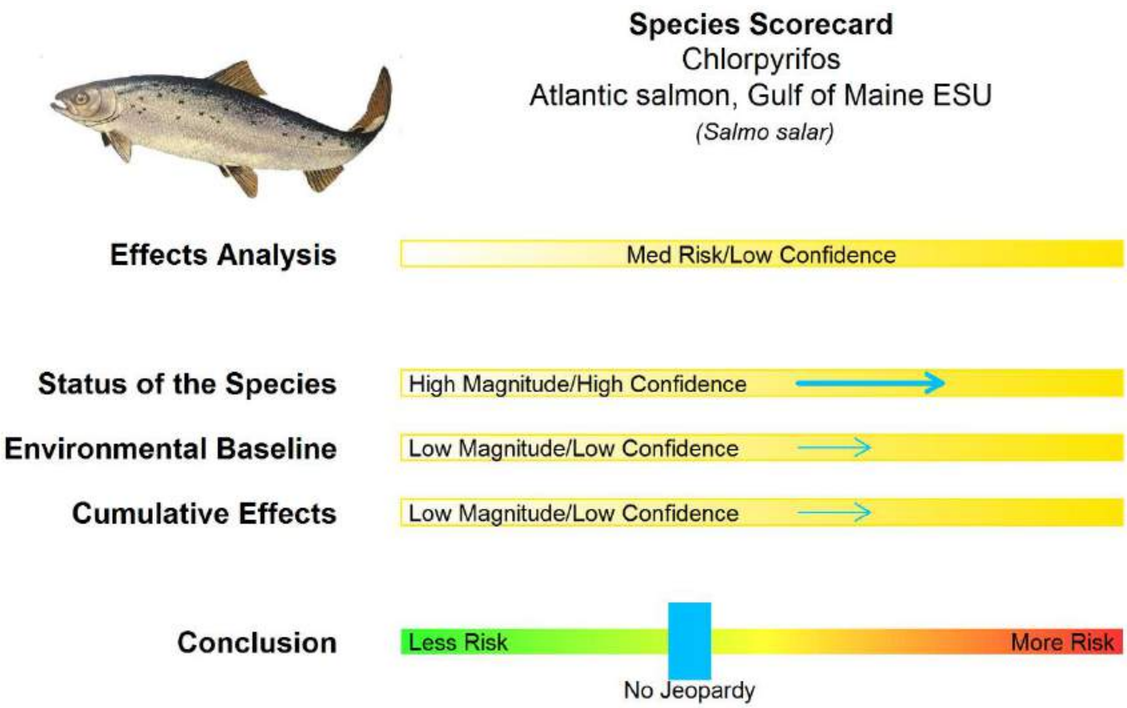

Figure 3. Species Score Card; Atlantic salmon, Gulf of Maine Evolutionarily Significant Unit (ESU); Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- Salmon occupying coastal, shallow areas may experience reduced abundance.
- Anticipated effects may include death, reduced cholinesterase activity, reduced prey abundance, and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Abundance is declining, low resilience to disturbance, sustained by hatcheries
- Endangered species population estimated at 0.3% of historical levels
- Proposed action may hinder attainment of recovery goals in coastal areas

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters not anticipated to affect species
- Environmental mixtures not anticipated to substantially affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures in marine areas uncertain to affect species
- No anticipated hydrologic effects in marine waters that would affect species

<u>Conclusion:</u> In their marine habitats, we find a low likelihood of exposure and effects to the species as a whole based on low confidence in exposure concentrations predicted for these open water saltwater habitats. The species is most at risk while in coastal, estuarine areas where they spend a small portion of their lives. Potential reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

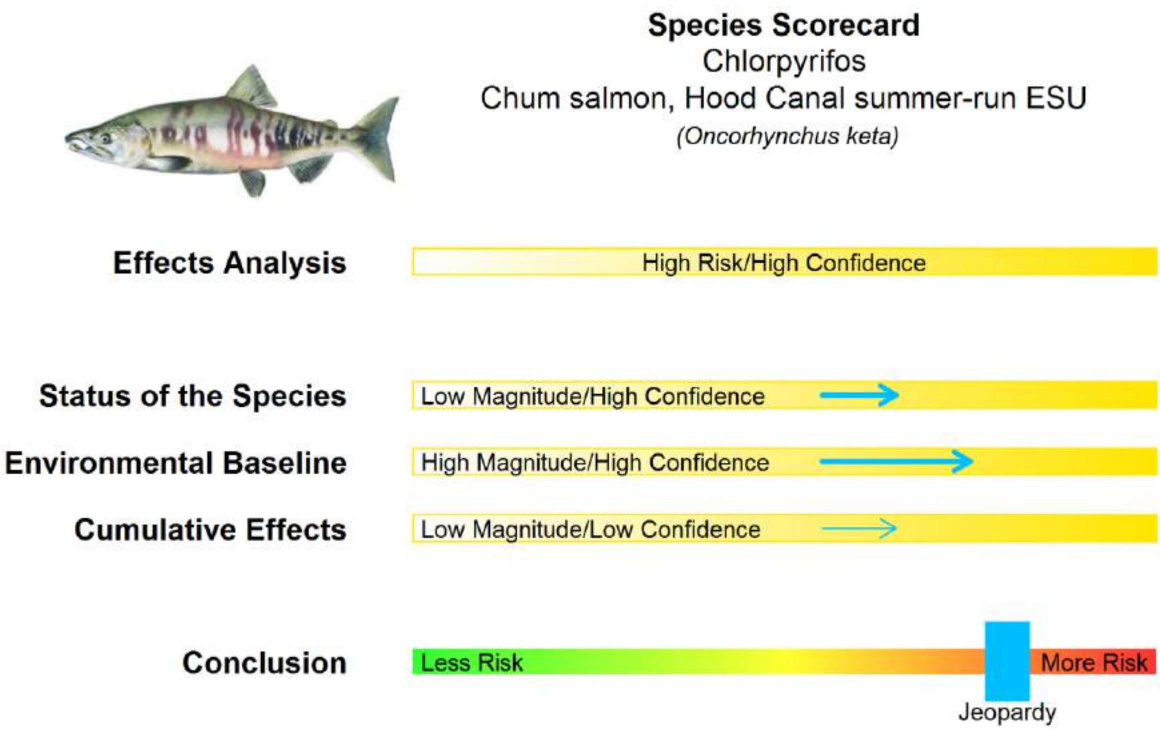

Figure 4. Species Score Card; Chum salmon, Hood Canal summer-run ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Salmon occupying freshwater and nearshore areas likely experience reduced abundance and productivity.
- Anticipated effects include death, reduced cholinesterase activity, reduced prey abundance, impaired swimming, and reduced productivity.

<u>Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence</u>

- Stable to increasing abundance trend, increasing population productivity
- Threatened species; 6 of 15 populations extirpated or nearly extirpated
- Proposed action may hinder attainment of some recovery goals

<u>Environmental Baseline: Minimal increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures anticipated in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures likely
- Anticipated hydrologic effects in freshwater areas may affect species

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species as a whole based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in freshwater and nearshore areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

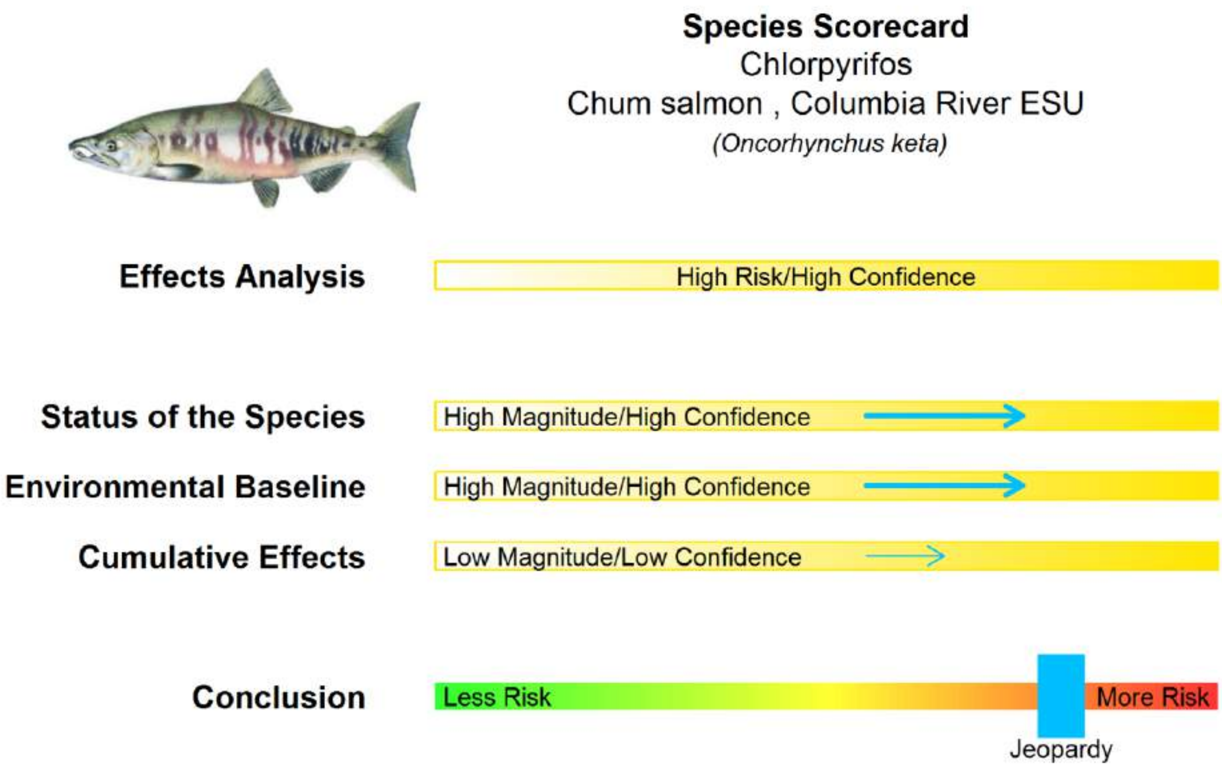

Figure 5. Species Score Card; Chum salmon, Columbia River ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Declining abundance trends, high risk of extinction
- Threatened species; 7 of 16 populations are functionally extinct
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Minimal increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures anticipated in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas that may affect species

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy**</u>

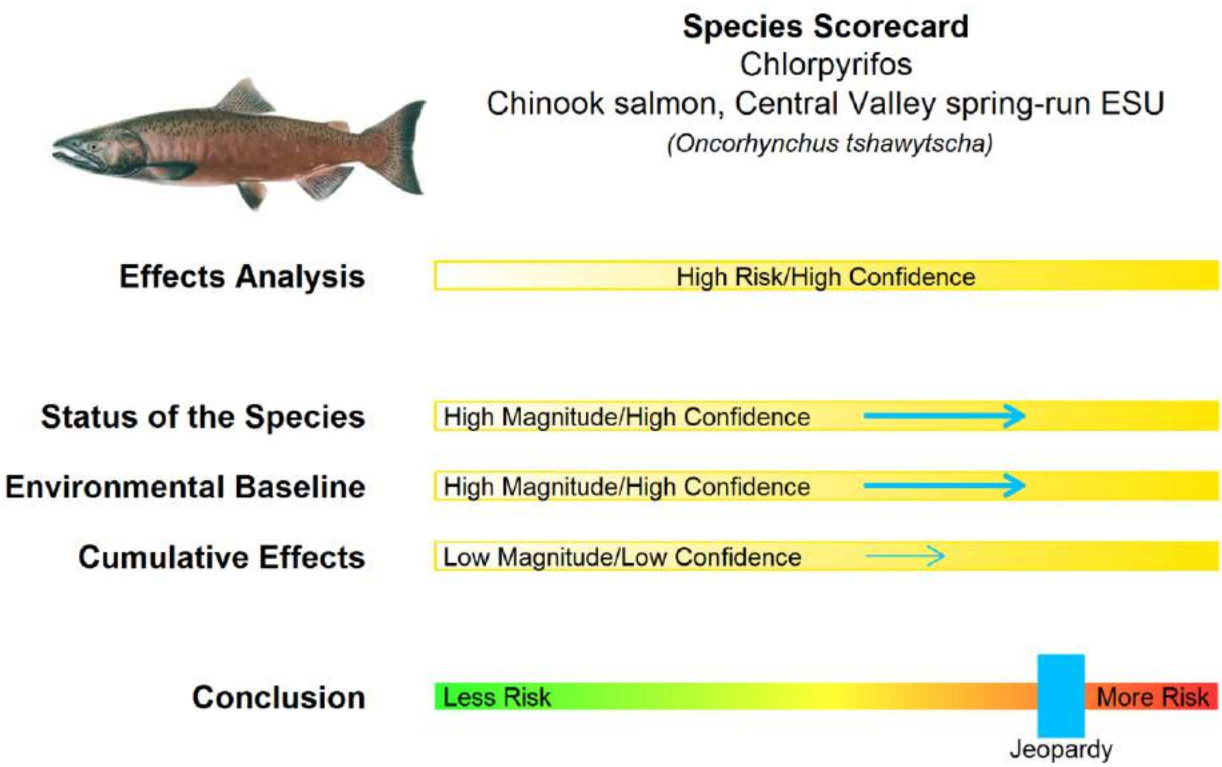

Figure 6. Species Score Card; Chinook salmon, Central Valley spring-run ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Stable to declining abundance trends, low abundances and fragmented populations
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy**</u>

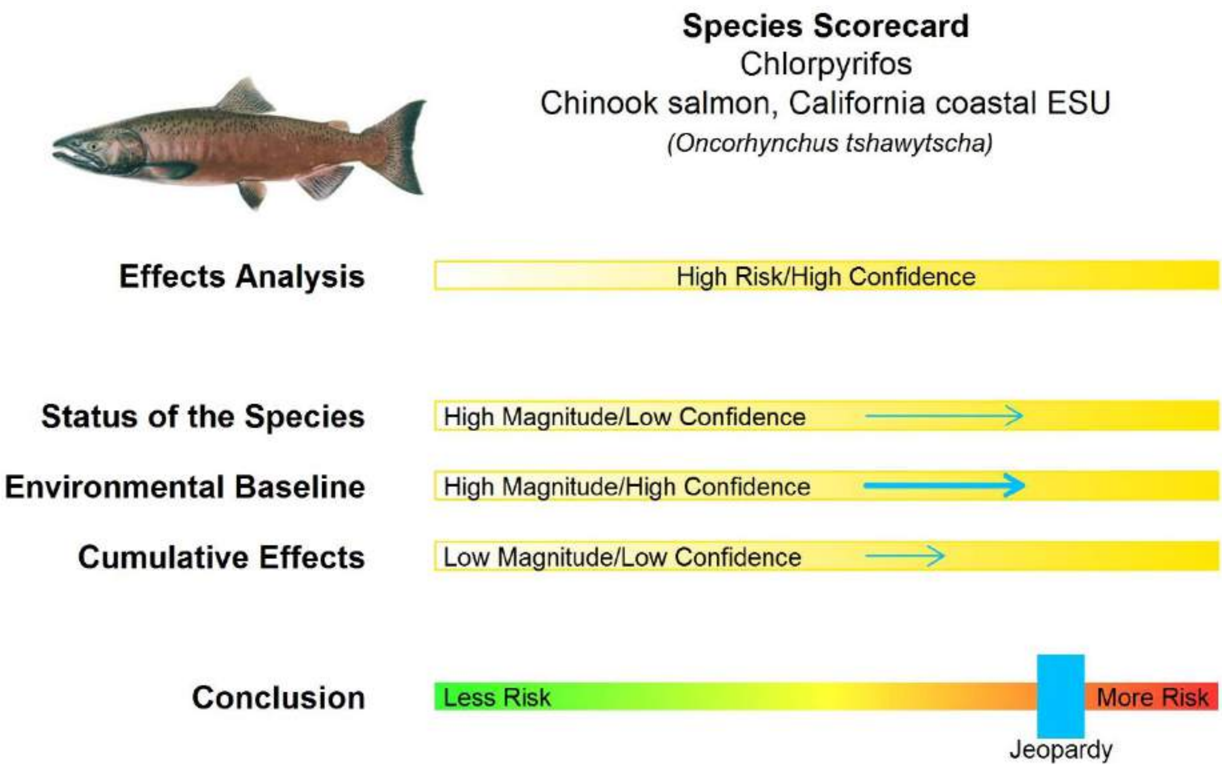

Figure 7. Species Score Card; Chinook salmon, California coastal ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; High magnitude/ Low confidence

- One population with greater than 1000 spawners, declining trends in abundance
- Threatened
- Some recovery criteria not met, yet reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

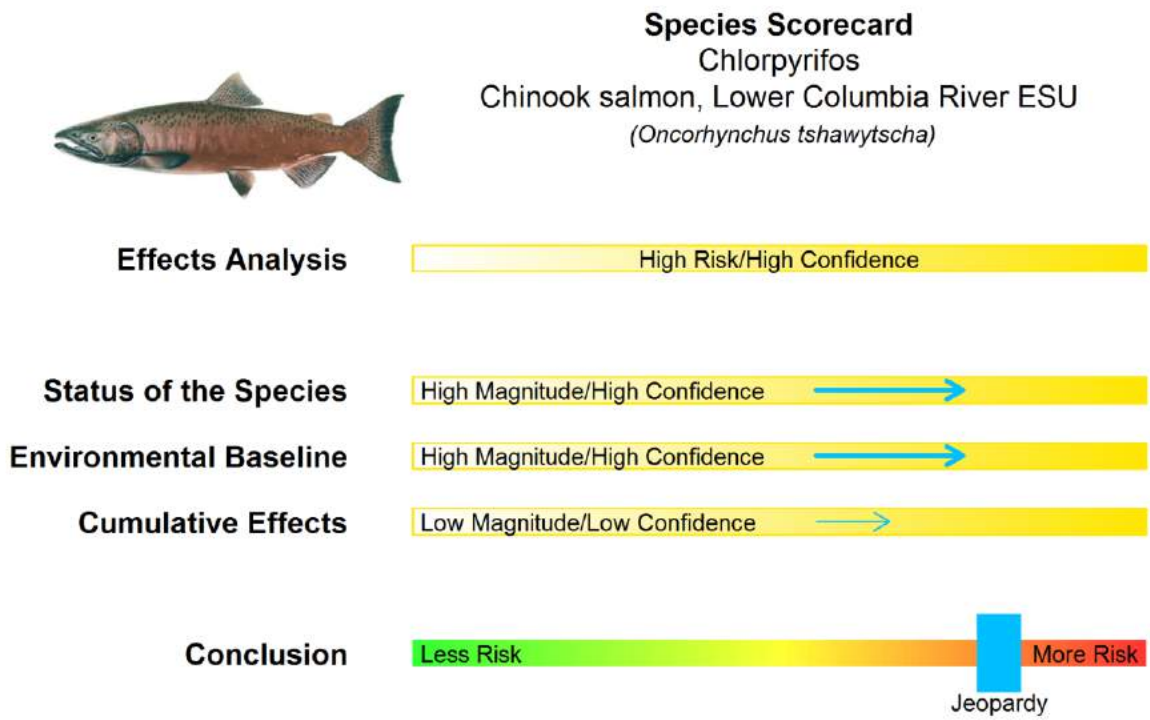

Figure 8. Species Score Card; Chinook salmon, Lower Columbia River ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Declining trends in abundance, one self-sustaining population, low genetic diversity
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

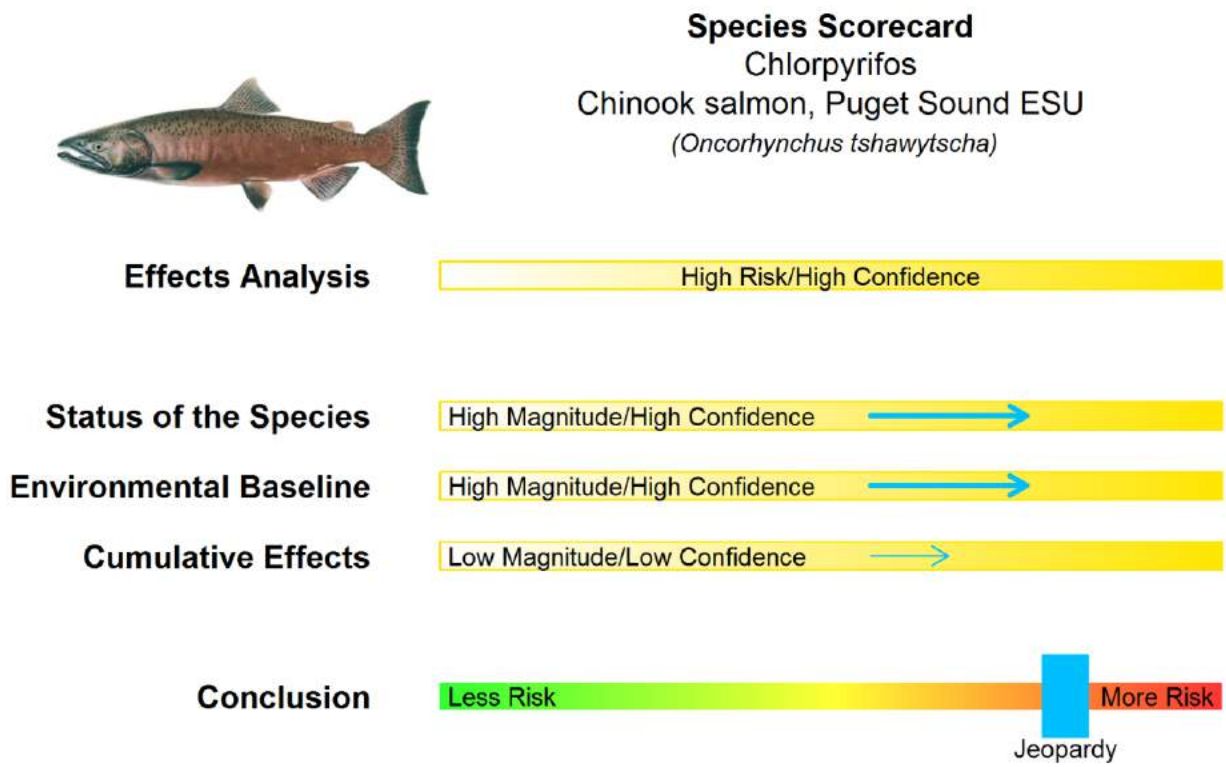

Figure 9. Species Score Card; Chinook salmon, Puget Sound ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Half of the populations declining and half increasing in abundance
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

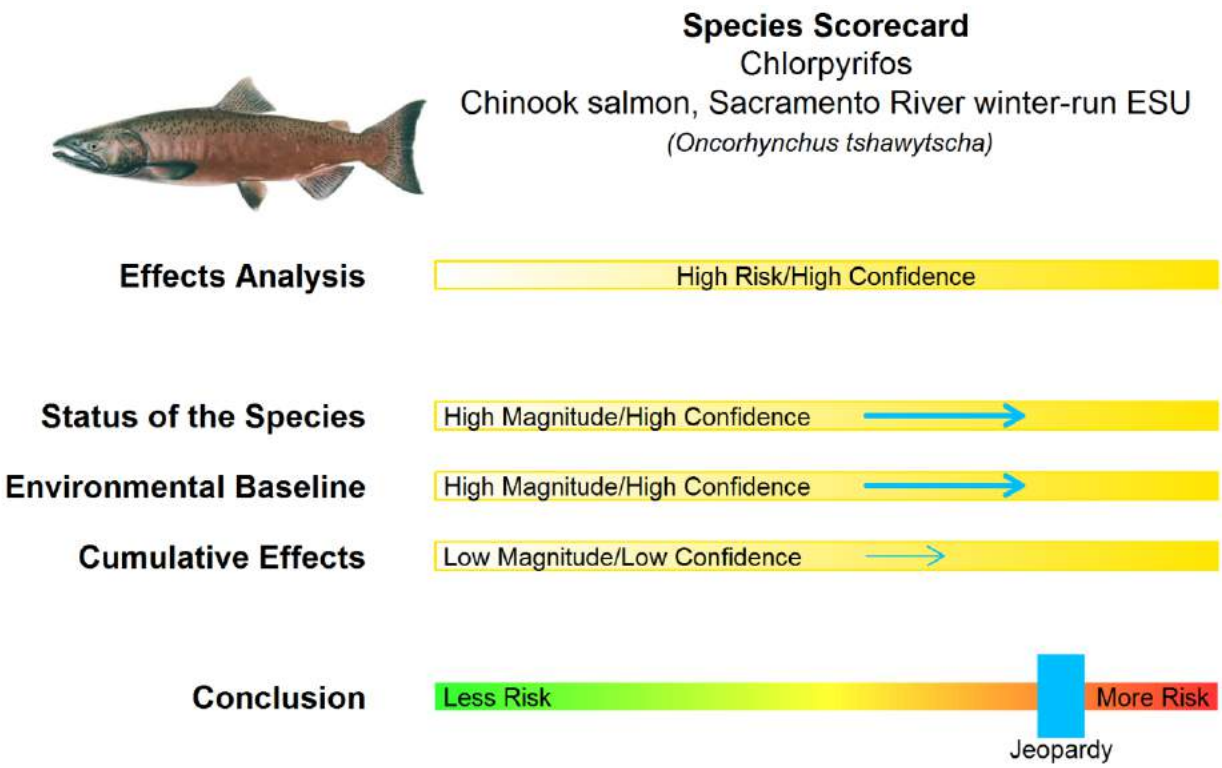

Figure 10. Species Score Card; Chinook salmon, Sacramento River winter-run ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- One extant population, declining abundance trends, hatchery-supported
- Endangered species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy**</u>
