Figure 11. Species Score Card; Chinook salmon, Snake River fall-run ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence

- Stable to increasing abundance trends, moderate extinction risk, hatchery supported
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

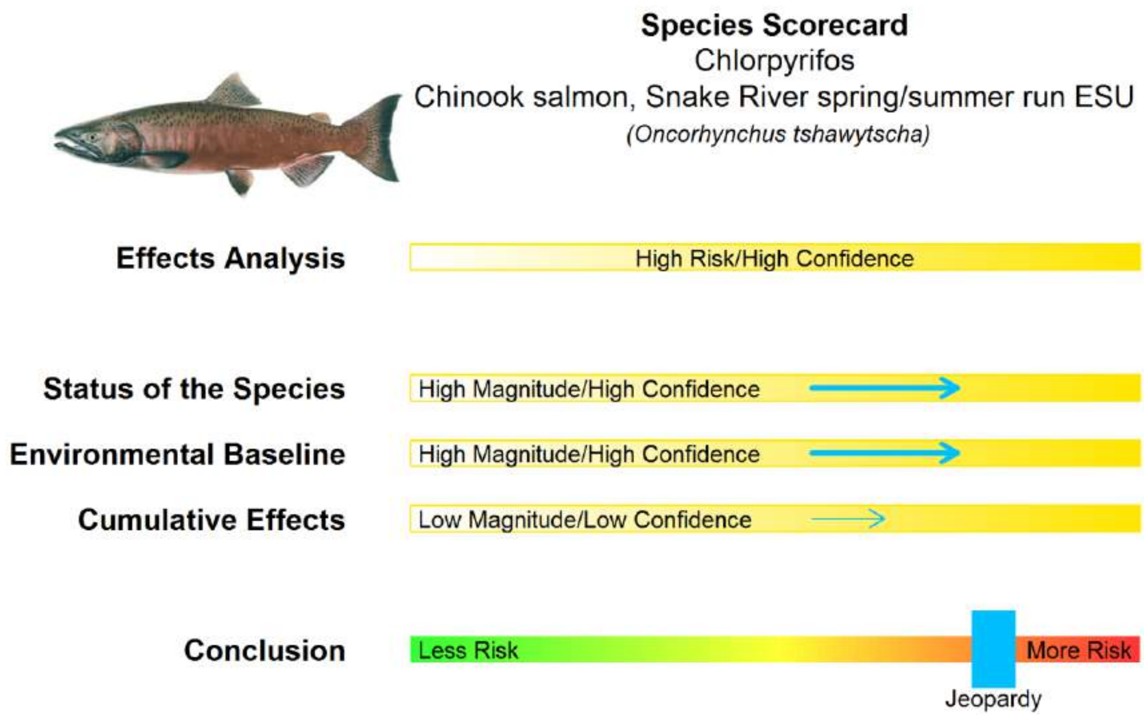

Figure 12. Species Score Card; Chinook salmon, Snake River spring/summer run ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence</u>

- Decreasing abundance trends, high extinction risk, moderate genetic diversity
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

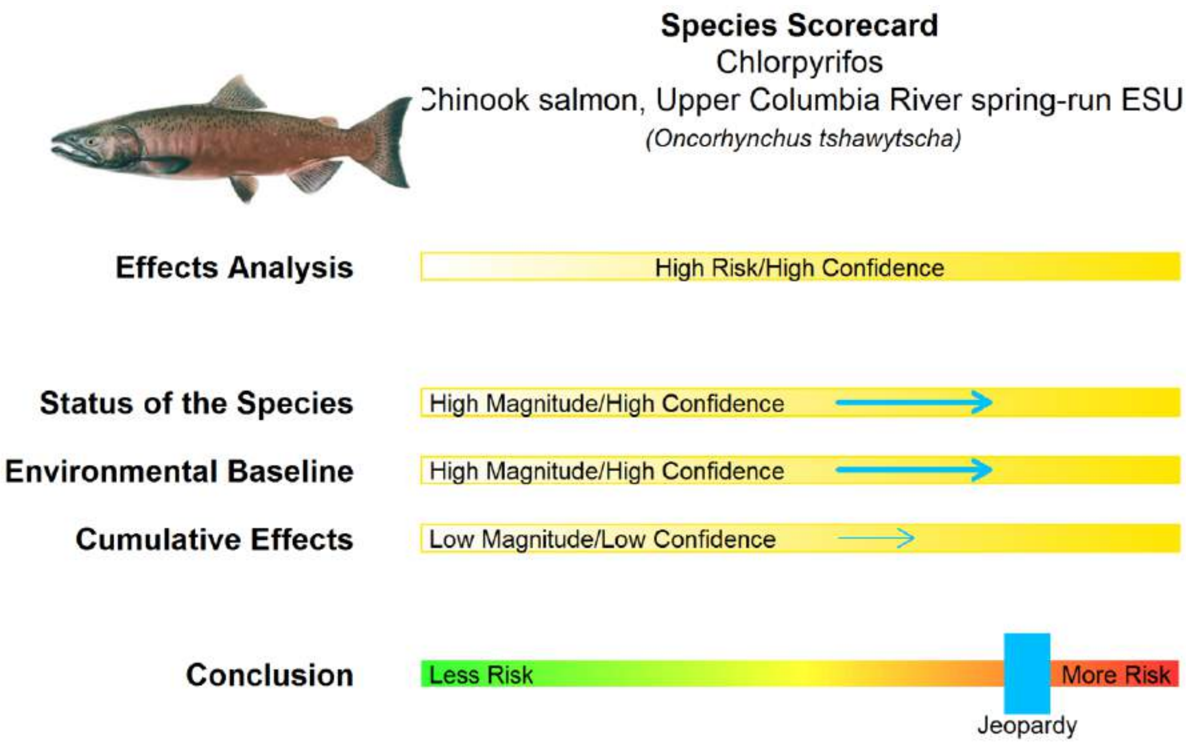

Figure 13. Species Score Card; Chinook salmon, Upper Columbia River spring-run ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Decreasing abundance trends, independent populations not replacing themselves
- Endangered species (all independent population experiencing low abundance)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy**</u>

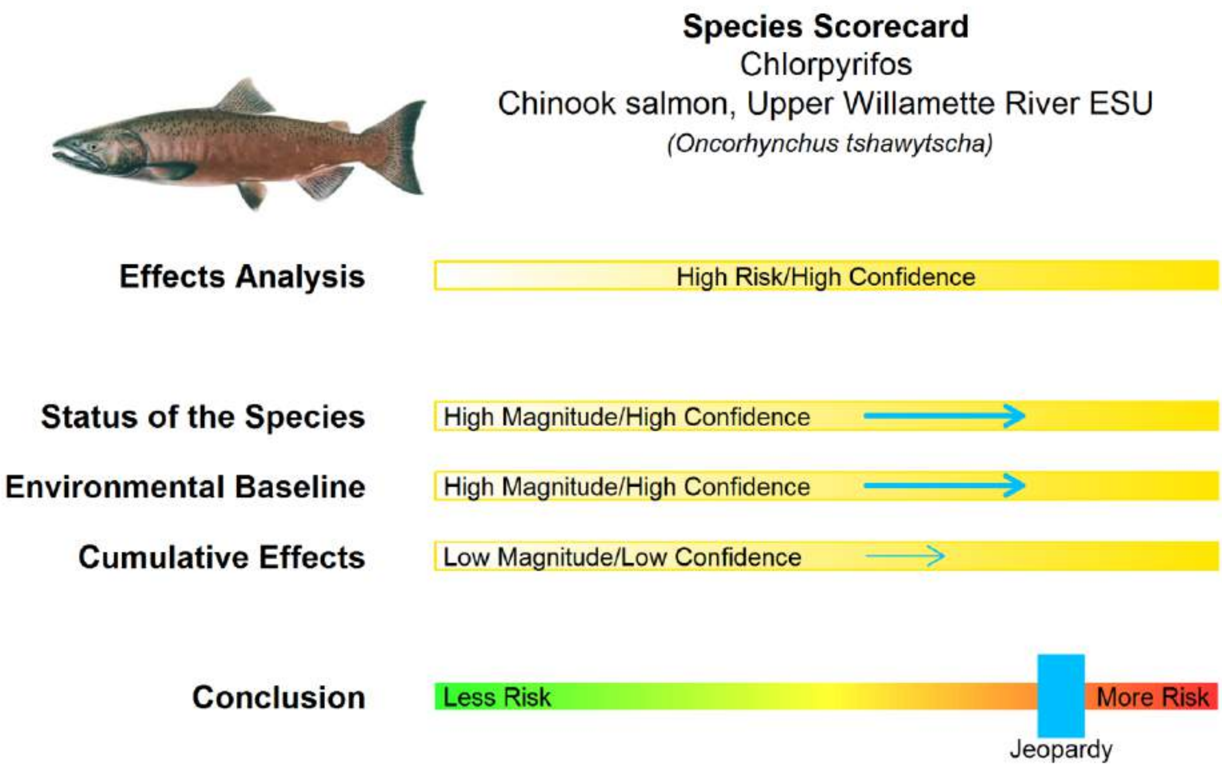

Figure 14. Species Score Card; Chinook salmon, Upper Willamette River ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; How magnitude/ High confidence</u>

- Decreasing abundance trends, 1 of 7 remaining naturally reproducing populations
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

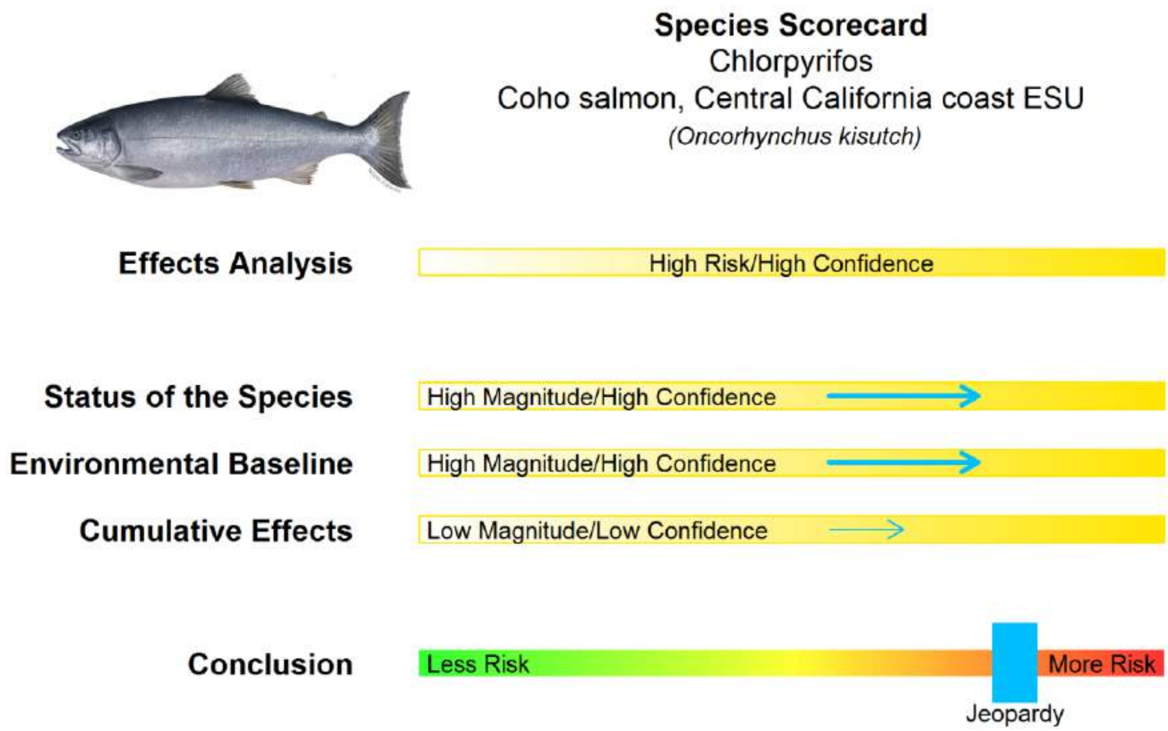

Figure 15. Species Score Card; Coho salmon, Central California coast ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; How magnitude/ High confidence</u>

- Stable population trend, fragmented populations, supported by hatchery propogation
- Endangered species (low abundances)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

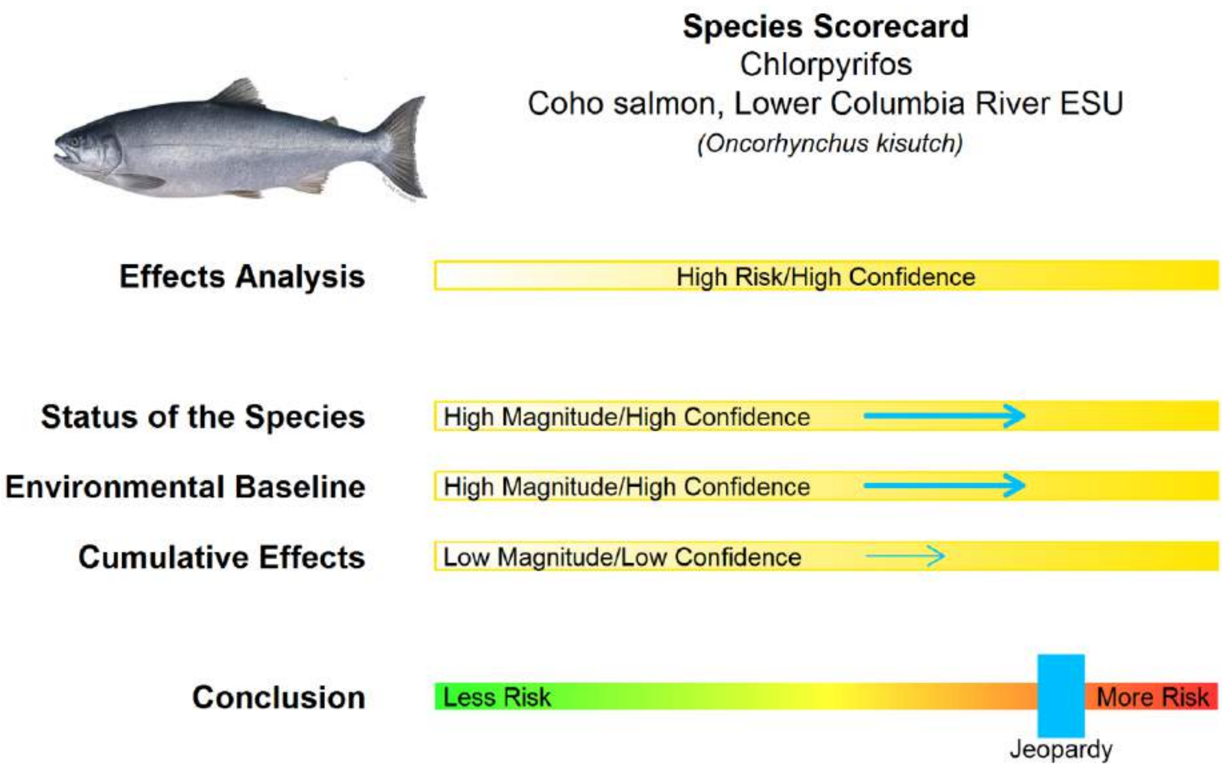

Figure 16. Species Score Card; Coho salmon, Lower Columbia River ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; How magnitude/ High confidence</u>

- Negative long/short term lambda projections; 2/25 populations exhibit natural production. Diveristy at high risk category.
- Endangered species (90% reduction in abundance of all independent populations)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

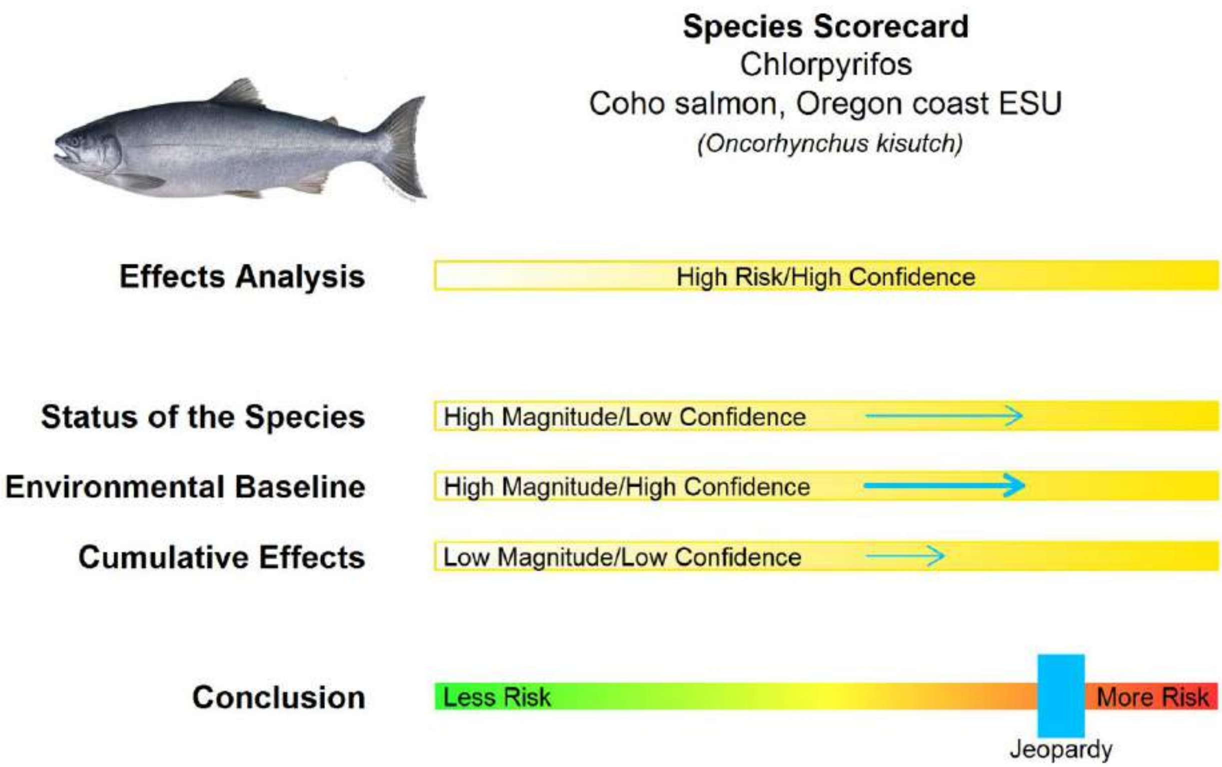

Figure 17. Species Score Card; Coho salmon, Oregon coast ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; How magnitude/ Low confidence

- Variable abundances with periods of severe declines. Negative long term trends negative
- Threatened (Severe reductions in ESU abundance compared to historical estimates)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

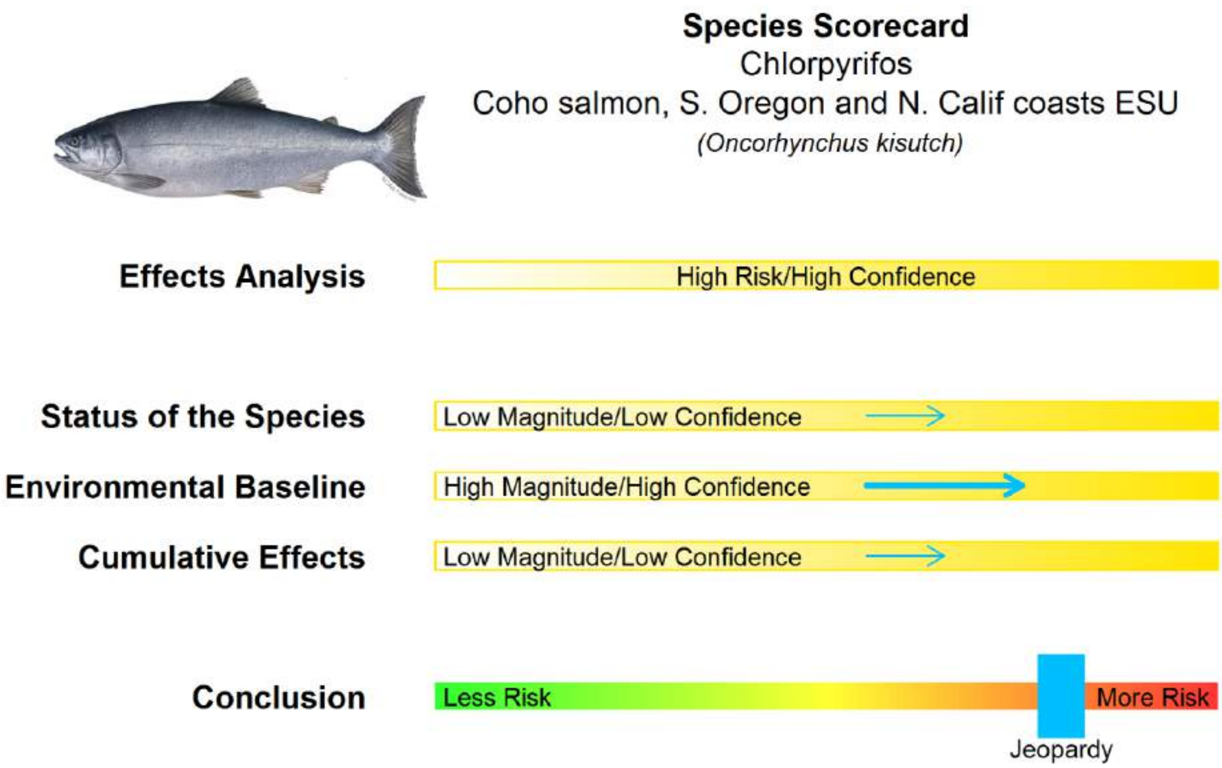

Figure 18. Species Score Card; Coho salmon, S. Oregon and N. Calif coasts ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Limited data on population abundance, thus trend data unavailable
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

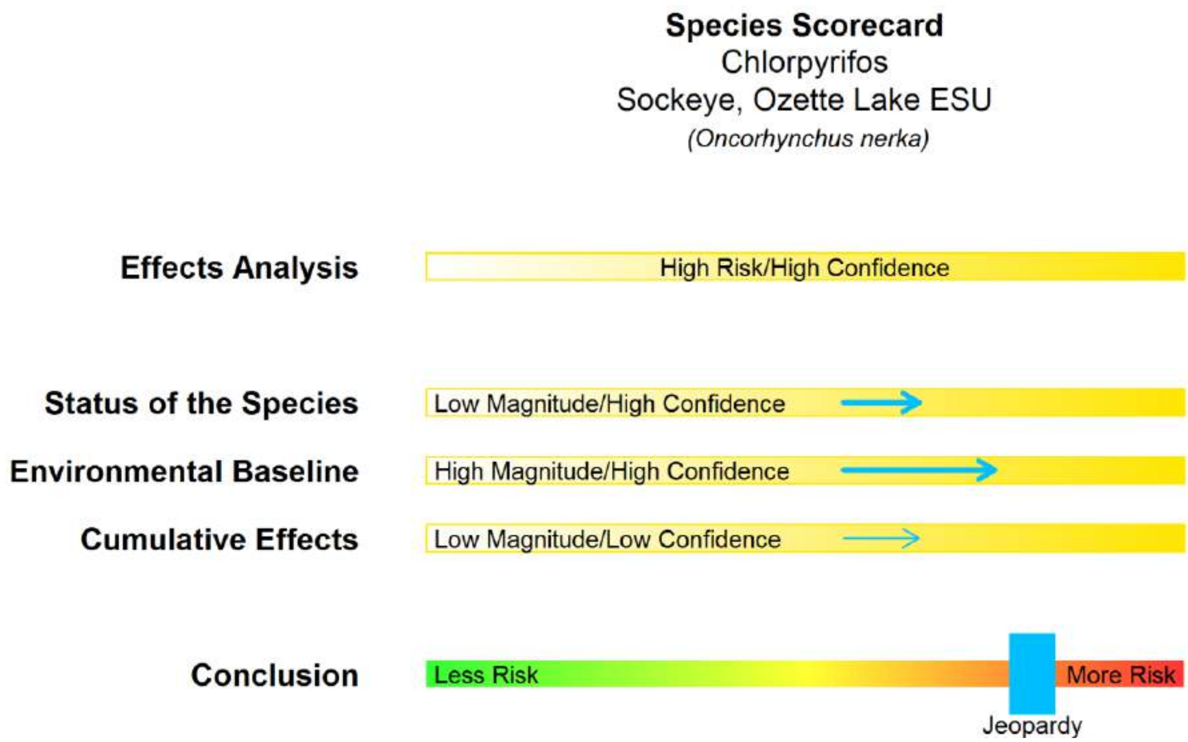

Figure 19. Species Score Card; Sockeye, Ozette Lake ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- Stable productivity rates; low genetic diversity and low resilience to future perturbations
- Threatened (abundance only 1% of historical levels)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

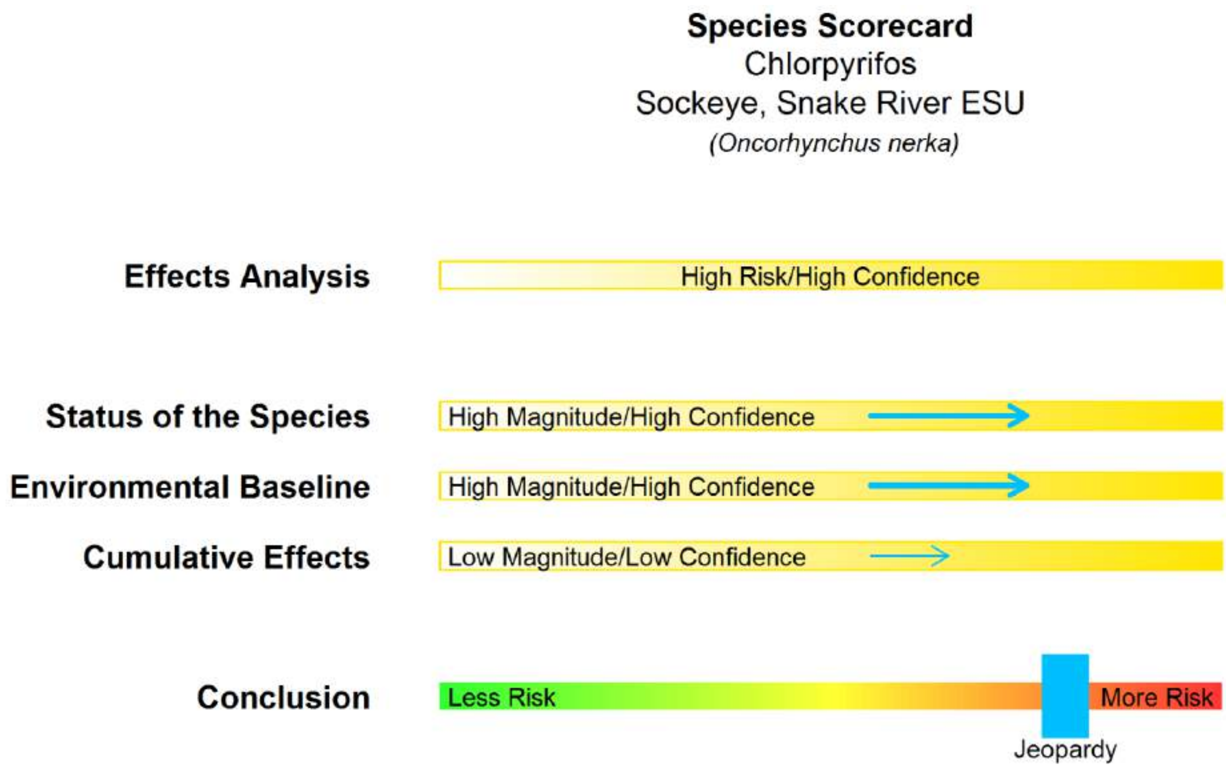

Figure 20. Species Score Card; Sockeye, Snake River ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- One population remaining supported by hatchery propagation. Increasing abundance, well below sustainable natural production. Low resilience to perturbations.
- Endangered (abundance only 1% of historical levels)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

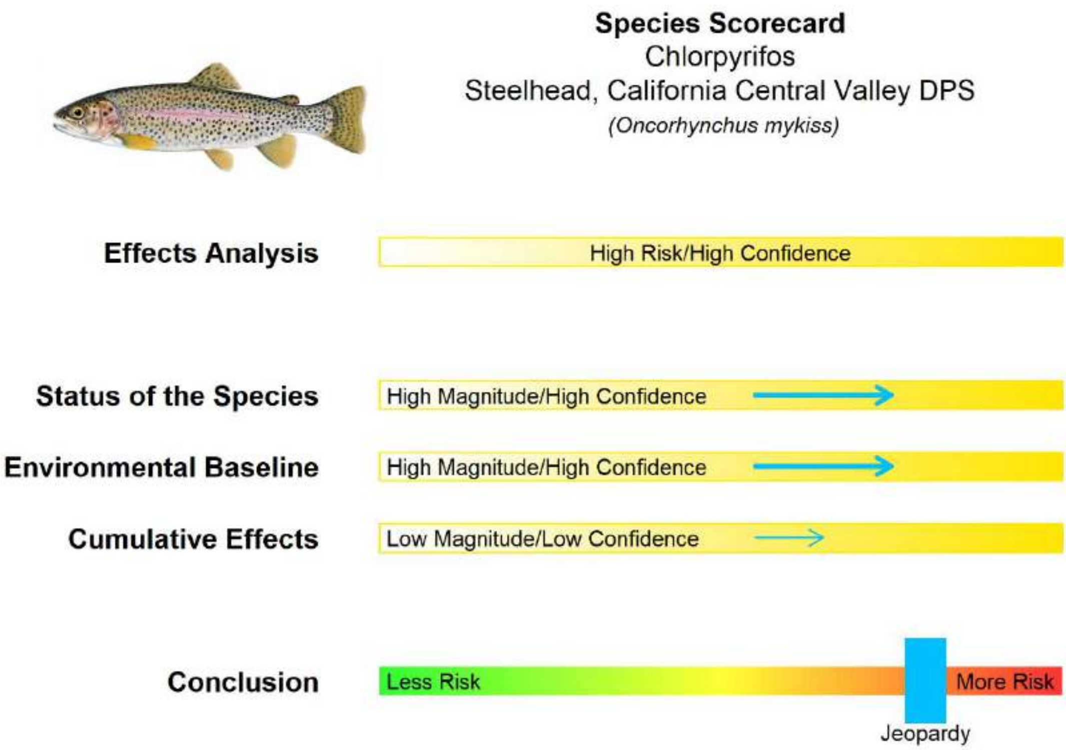

Figure 21. Species Score Card; Steelhead, California Central Valley Distinct Population Segment (DPS); Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Long-term trend of declining abundances and reduced genetic diversity. Populations supplemented by hatchery propogation.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

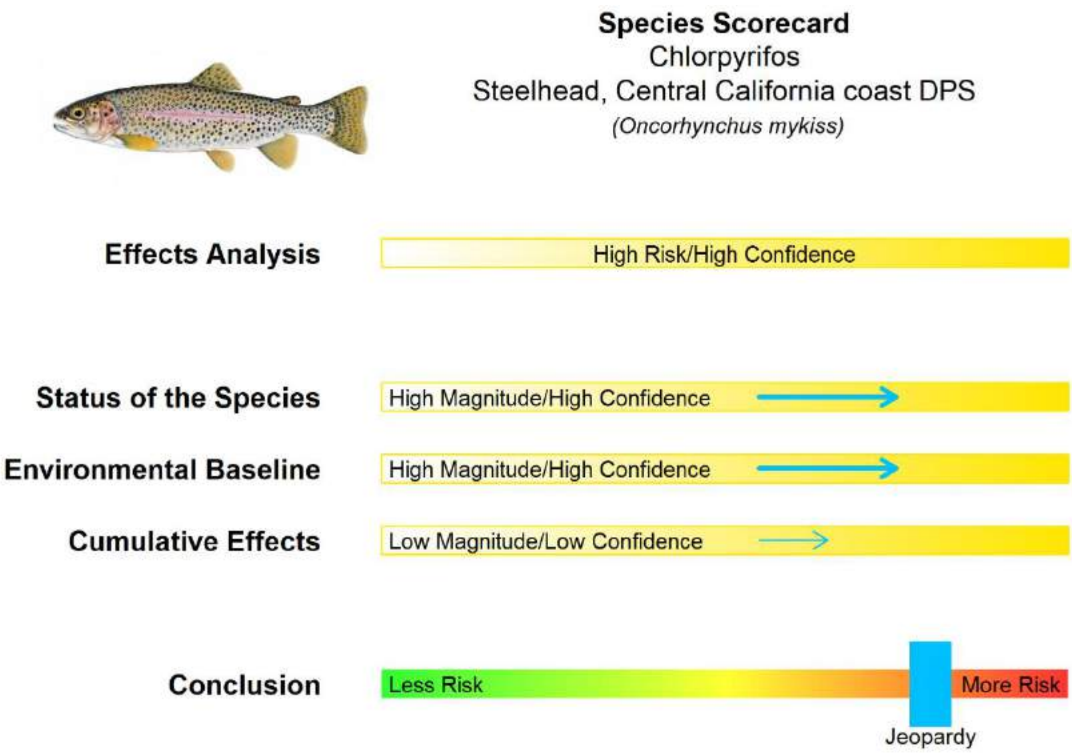

Figure 22. Species Score Card; Steelhead, Central California coast DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend uncertain. Population abundance supplemented by hatchery propagation. Populations likely not viable, and have lost spatial structure.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

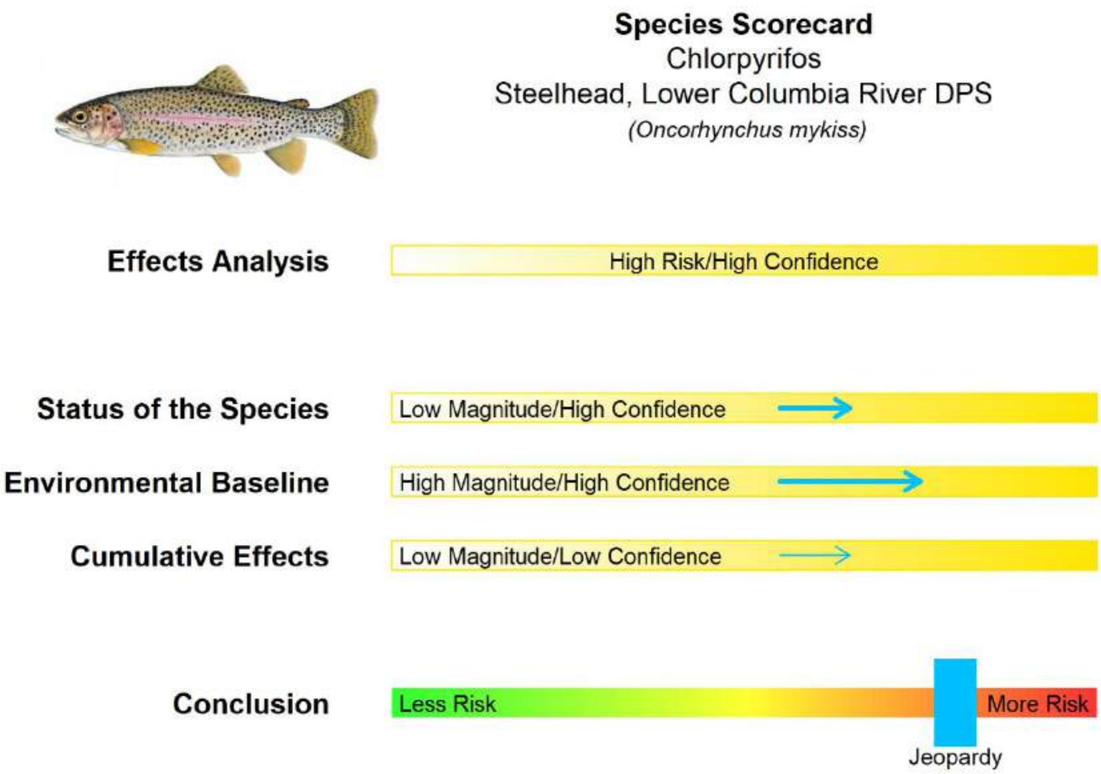

Figure 23. Species Score Card; Steelhead, Lower Columbia River DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence</u>

- 5-year population trend stable. Populations exhibit low genetic diversity and impacted by a loss of available habitat.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy**</u>

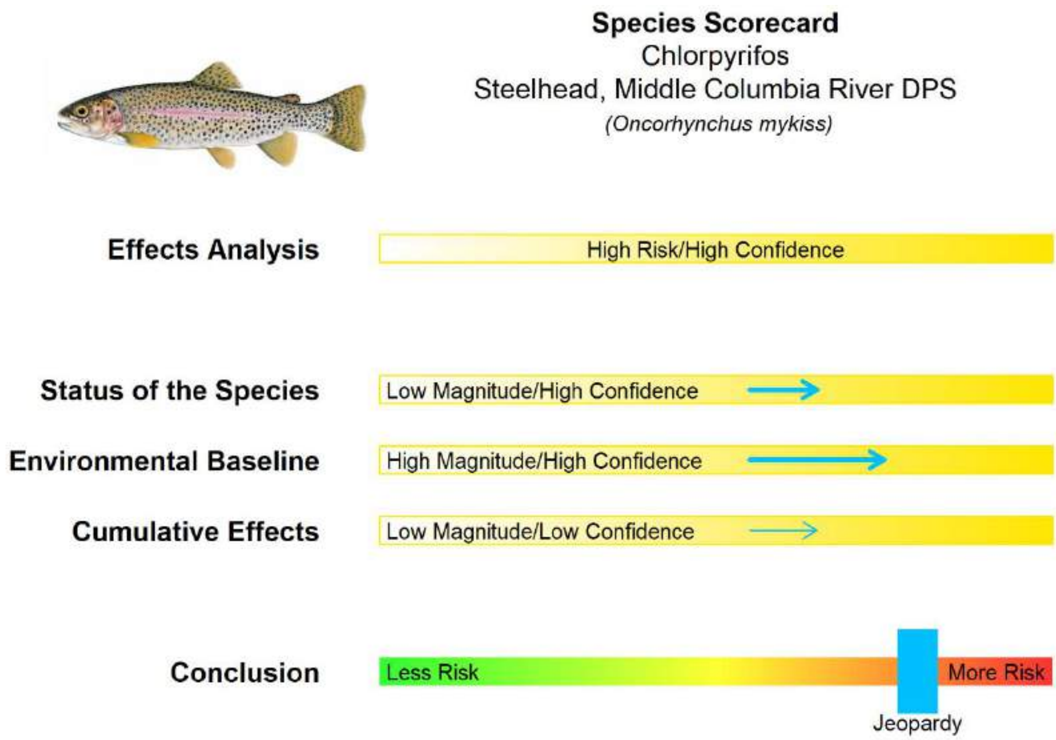

Figure 24. Species Score Card; Steelhead, Middle Columbia River DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence</u>

- 5-year population trend stable to improving; abundances remain low compared to historical numbers
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

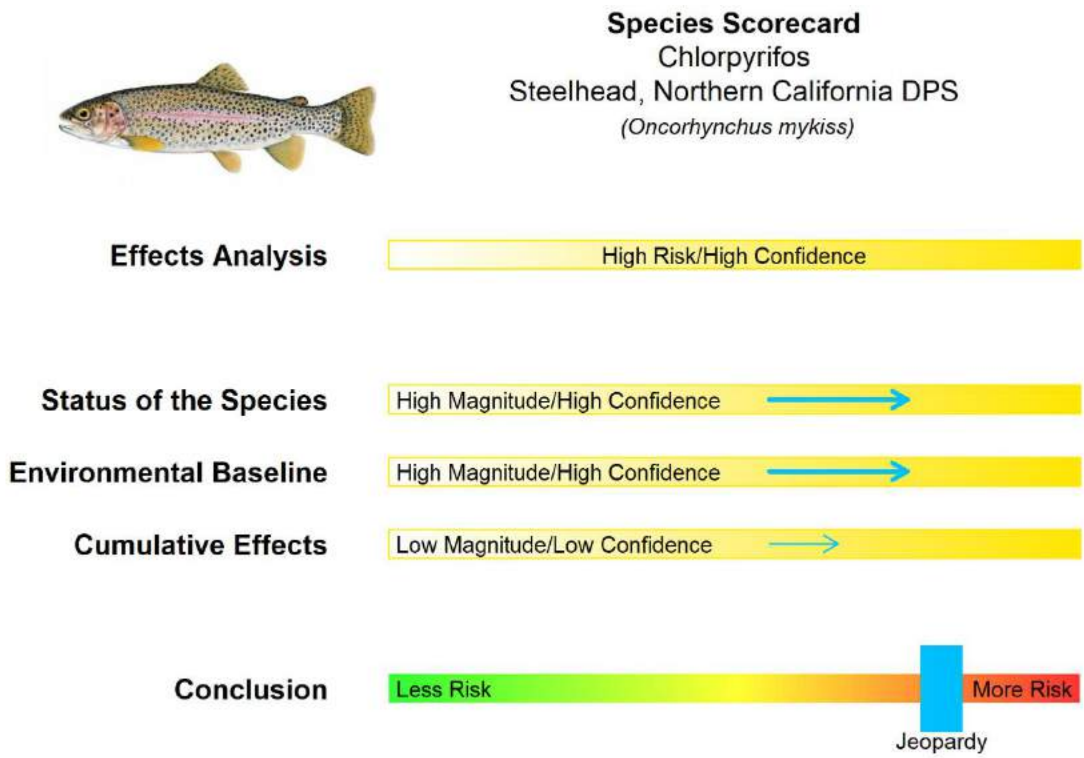

Figure 25. Species Score Card; Steelhead, Northern California DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Icreased risk of jeopardy; High magnitude/ High confidence

- Variable 5-year population abundance trends; Population supplemented by hatchery propagation. Populations exhibit low abundances and productivity.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

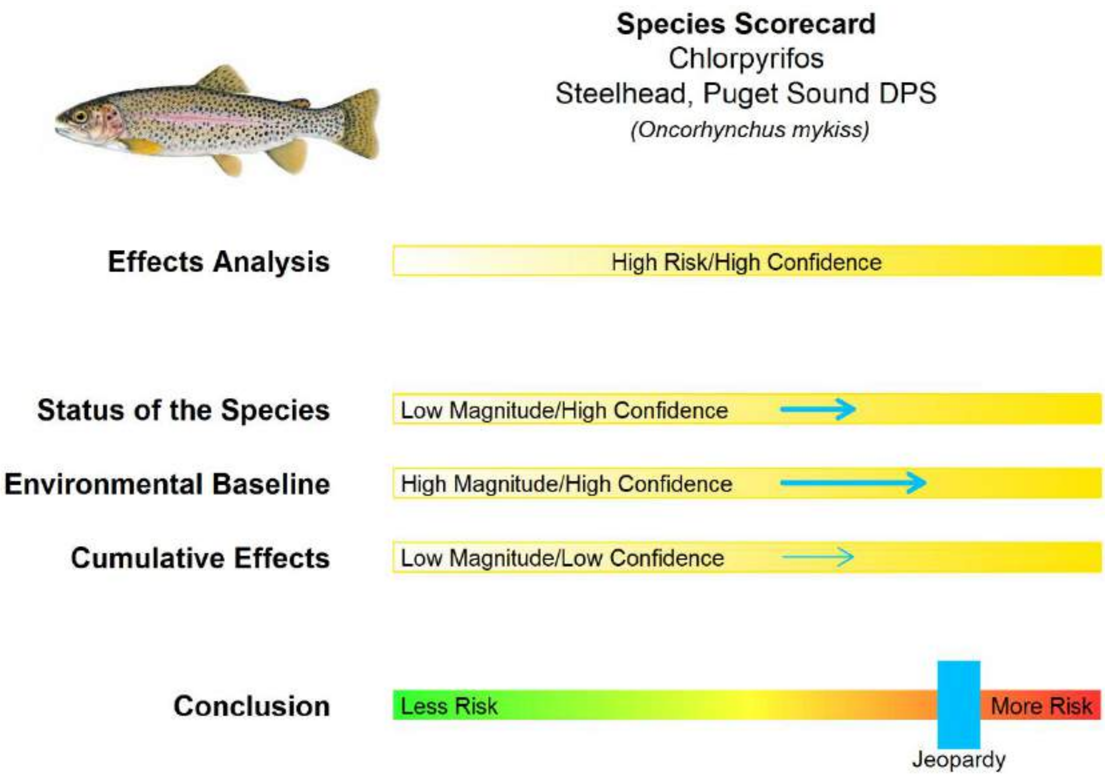

Figure 26. Species Score Card; Steelhead, Puget Sound DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- 5-year population trend stable, but populations have reduced genetic diversity
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

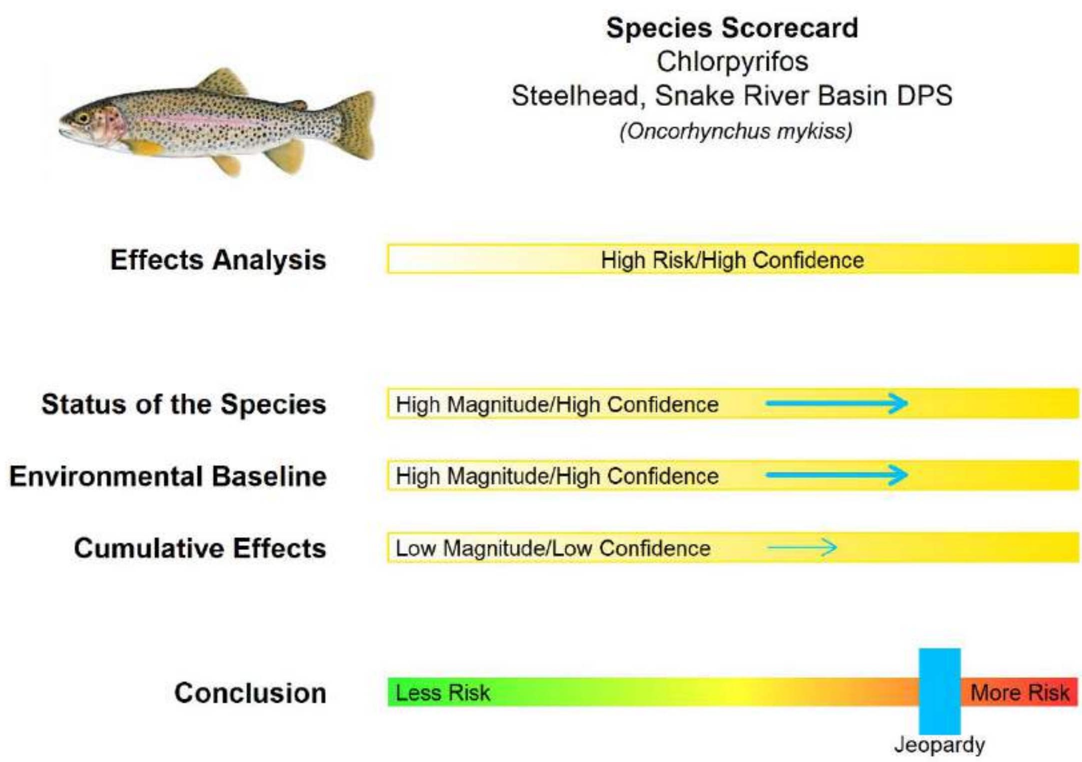

Figure 27. Species Score Card; Steelhead, Snake River Basin DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend stable to improving, but still in moderate danger of extinction. Overall abundances remain below thresholds necessary for recovery.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

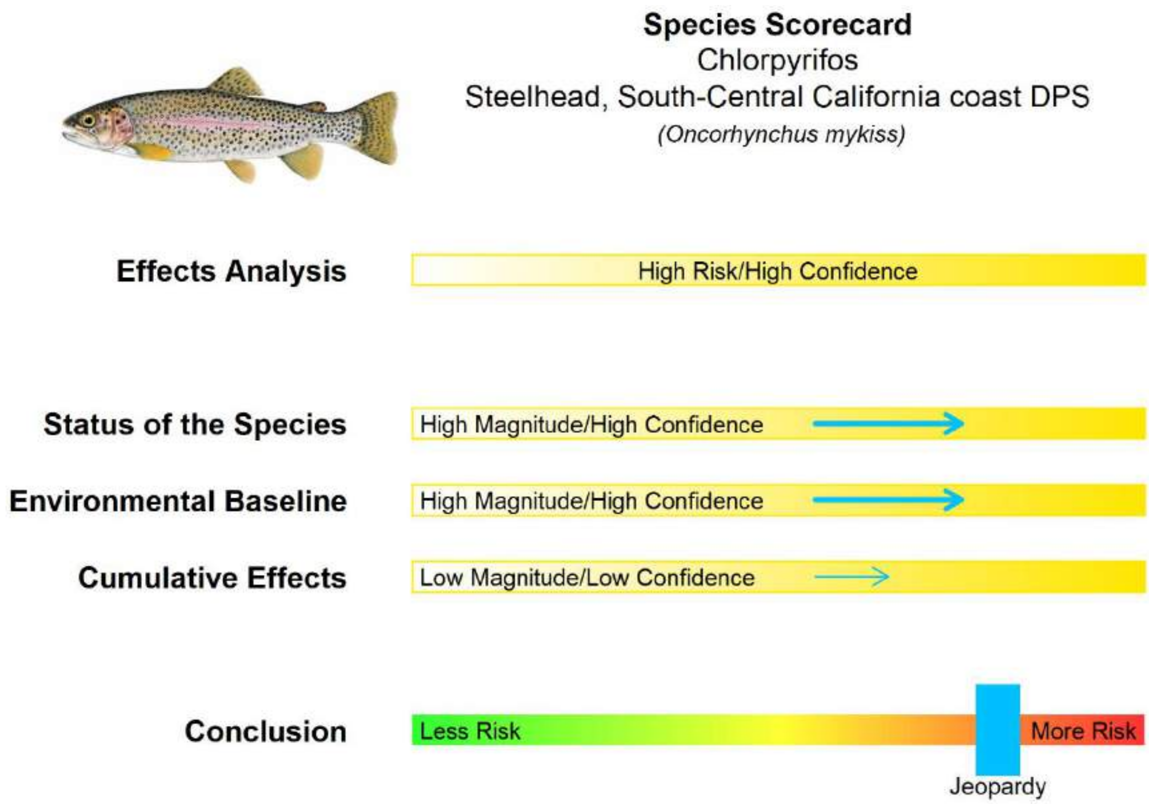

Figure 28. Species Score Card; Steelhead, South-Central California coast DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- 5-year population trend declining, depressed abundances.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

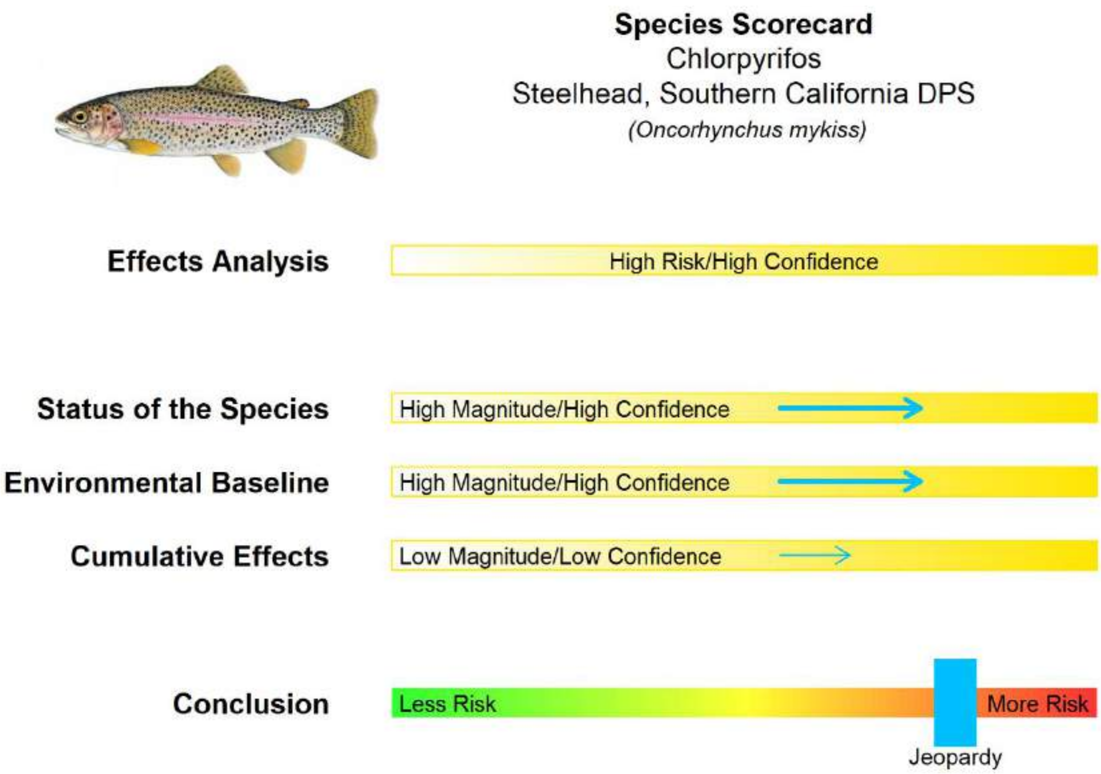

Figure 29. Species Score Card; Steelhead, Southern California DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend uncertain (large annual variations); supplemented by hatchery propagation; fragmented distributions.
- Endangered; Populations at extreme southern end of species' range
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

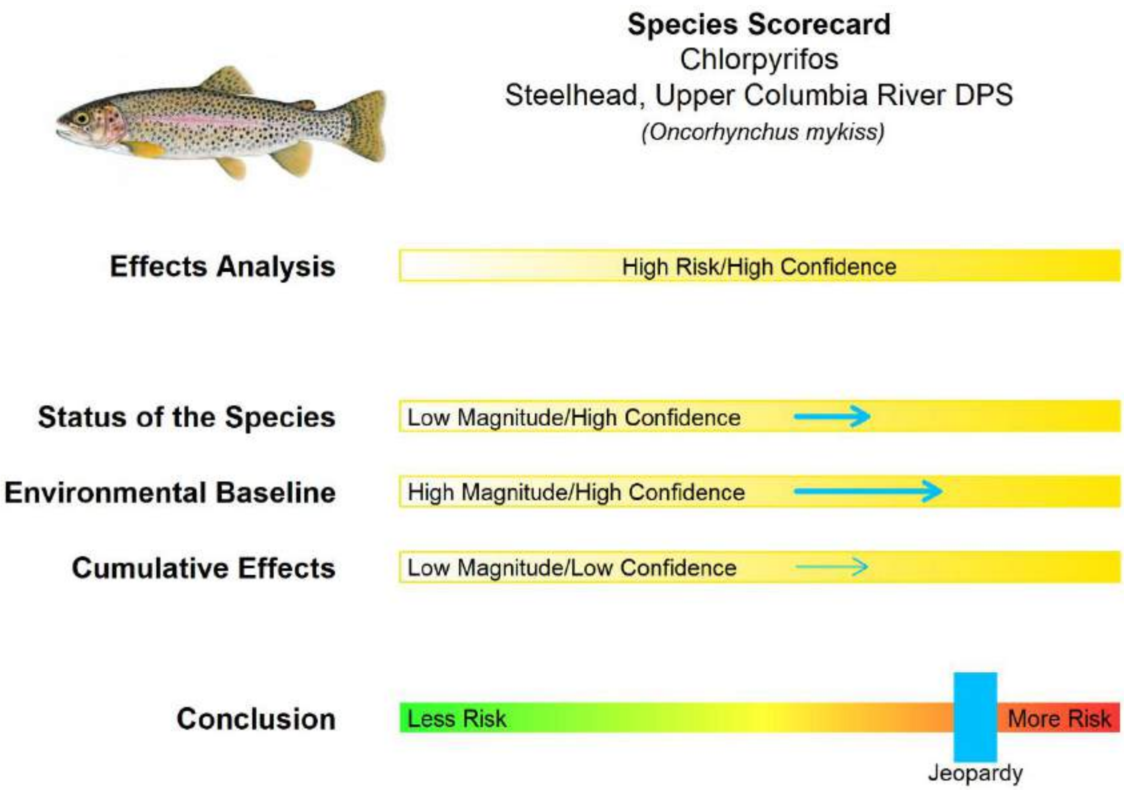

Figure 30. Species Score Card; Steelhead, Upper Columbia River DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend improving, but low genetic diversity.
- Threatened;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

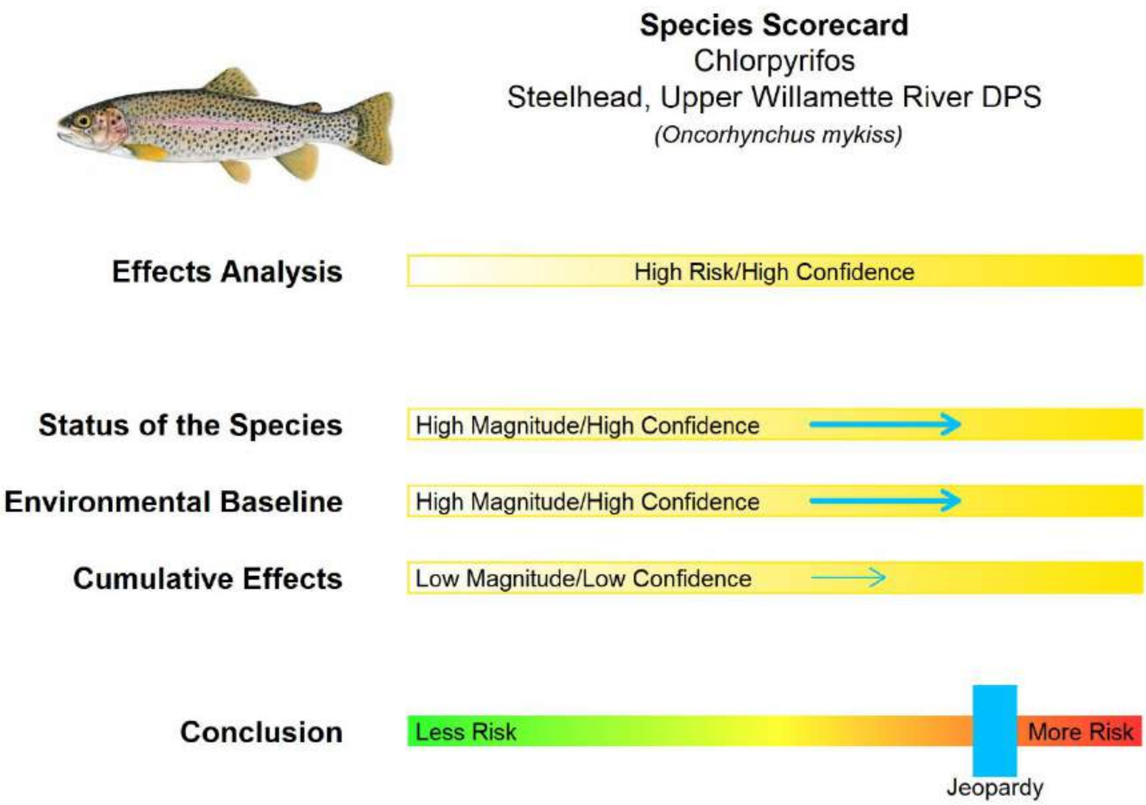

Figure 31. Species Score Card; Steelhead, Upper Willamette River DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- 5-year population trend declining, large fluctuations in abundances.
- Threatened;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

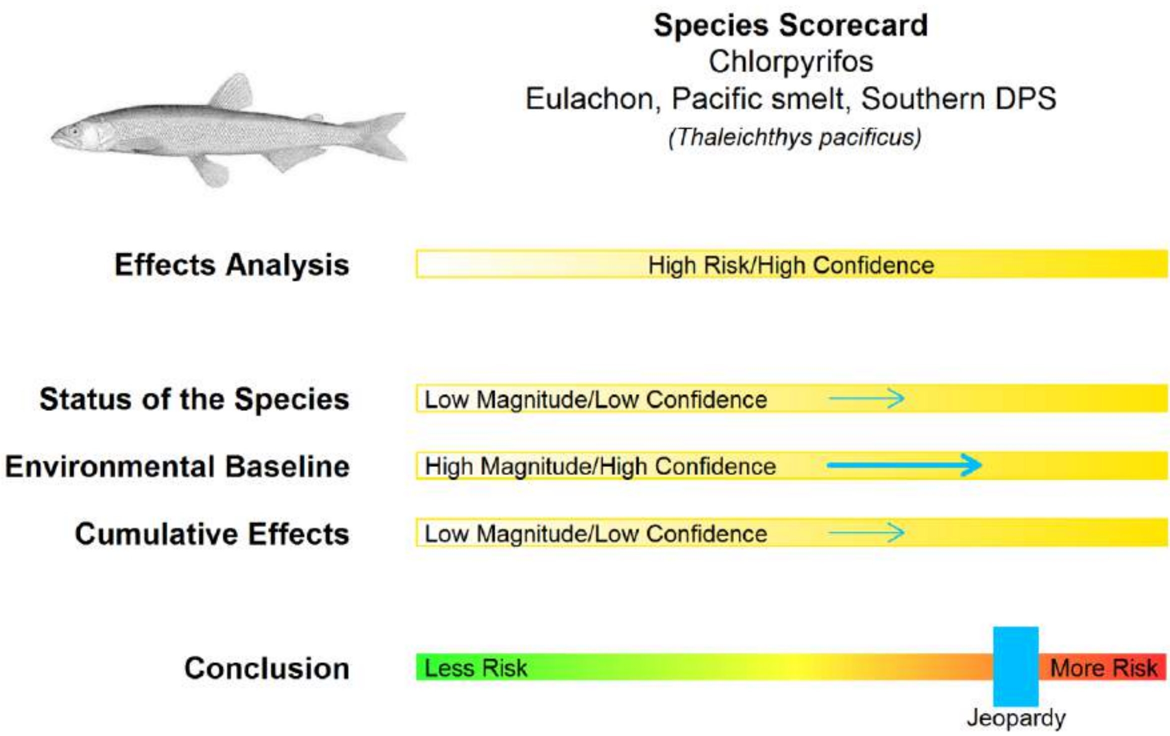

Figure 32. Species Score Card; Eulachon, Pacific smelt, Southern DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Population abundance improving, especially in the 2013–2015 return years; in upcoming return years population declines may be widespread from poor ocean conditions
- Threatened; severely depressed abundance mid-late 1990s to late 2000s;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

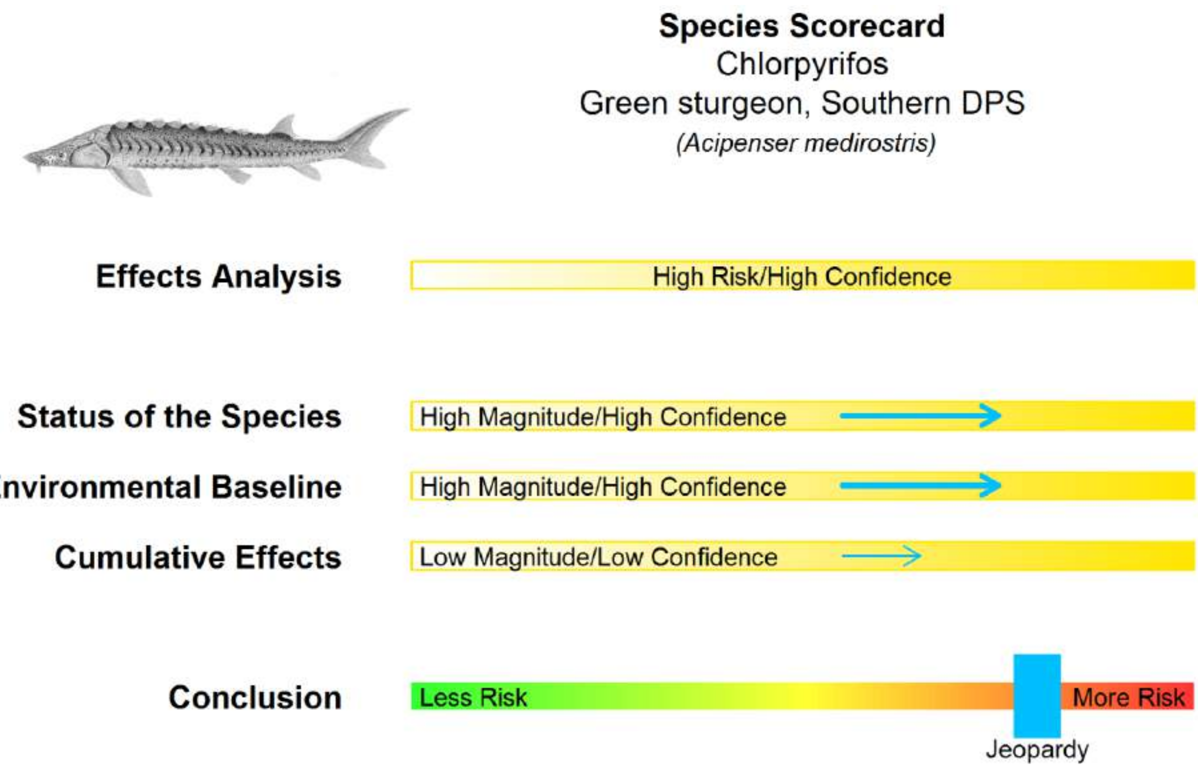

Figure 33. Species Score Card; Green sturgeon, Southern DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Small population size, little population data, few remaining spawning sites
- Threatened;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

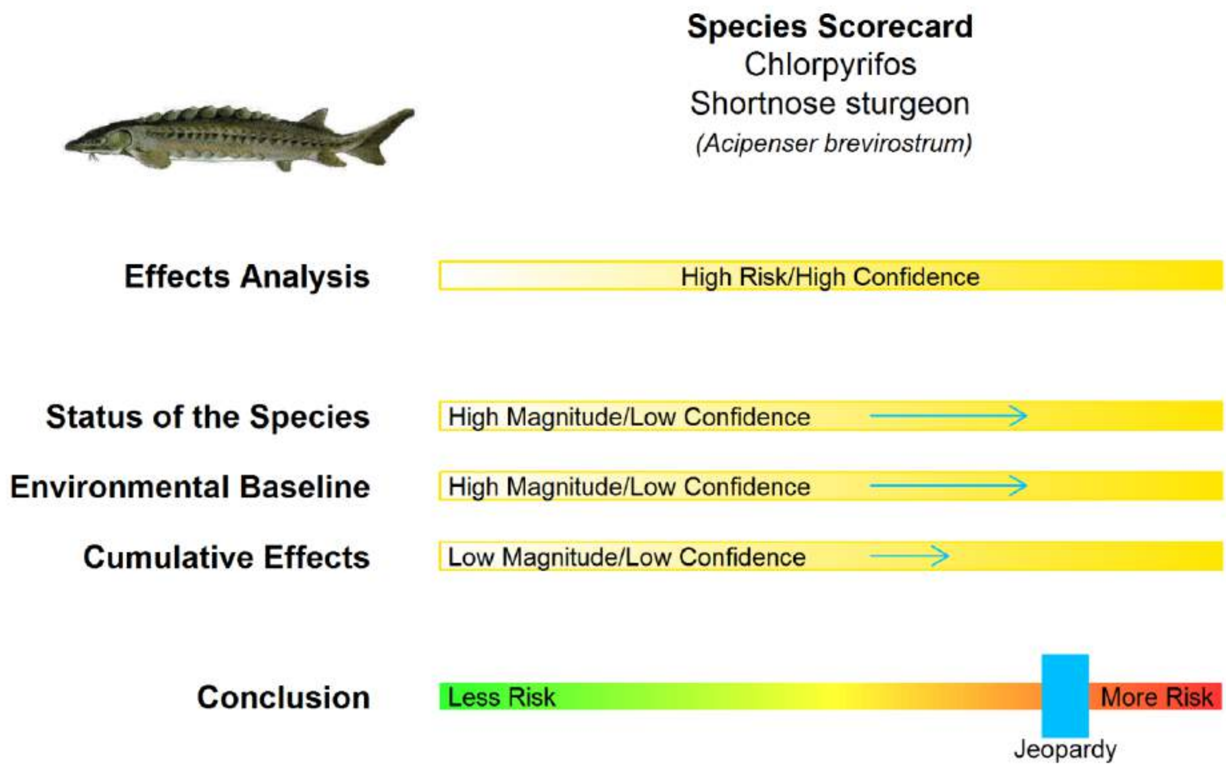

Figure 34. Species Score Card; Shortnose sturgeon; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence

- Stable to increasing populations, fragmented populations, only 12 known spawning sites
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

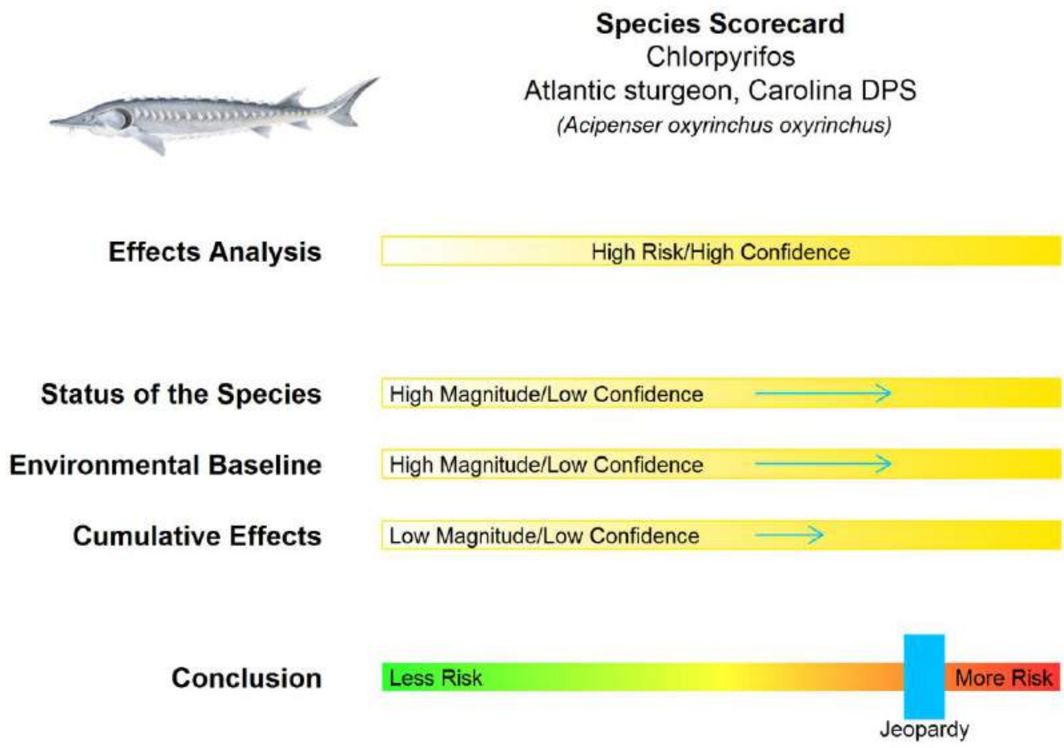

Figure 35. Species Score Card; Atlantic sturgeon, Carolina DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence</u>

- <3% of historical abundance
- Endangered;
- Recovery criteria not identified

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

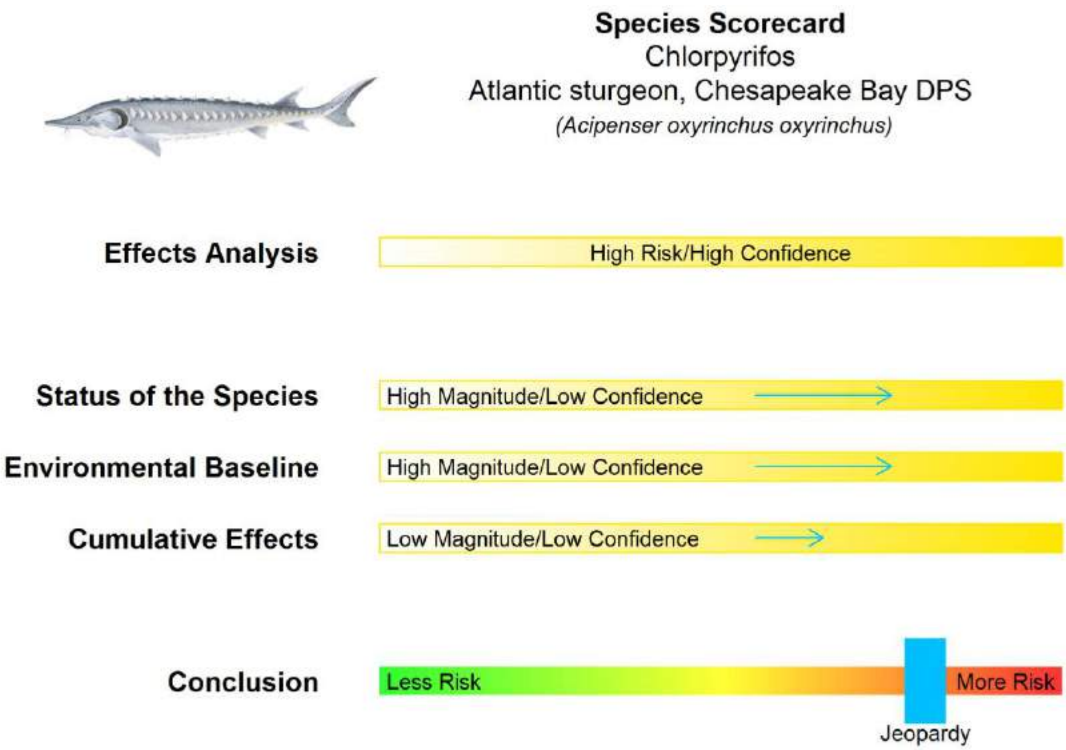

Figure 36. Species Score Card; Atlantic sturgeon, Chesapeake Bay DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence

- 4% of historical abundance, unknown population growth rate
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

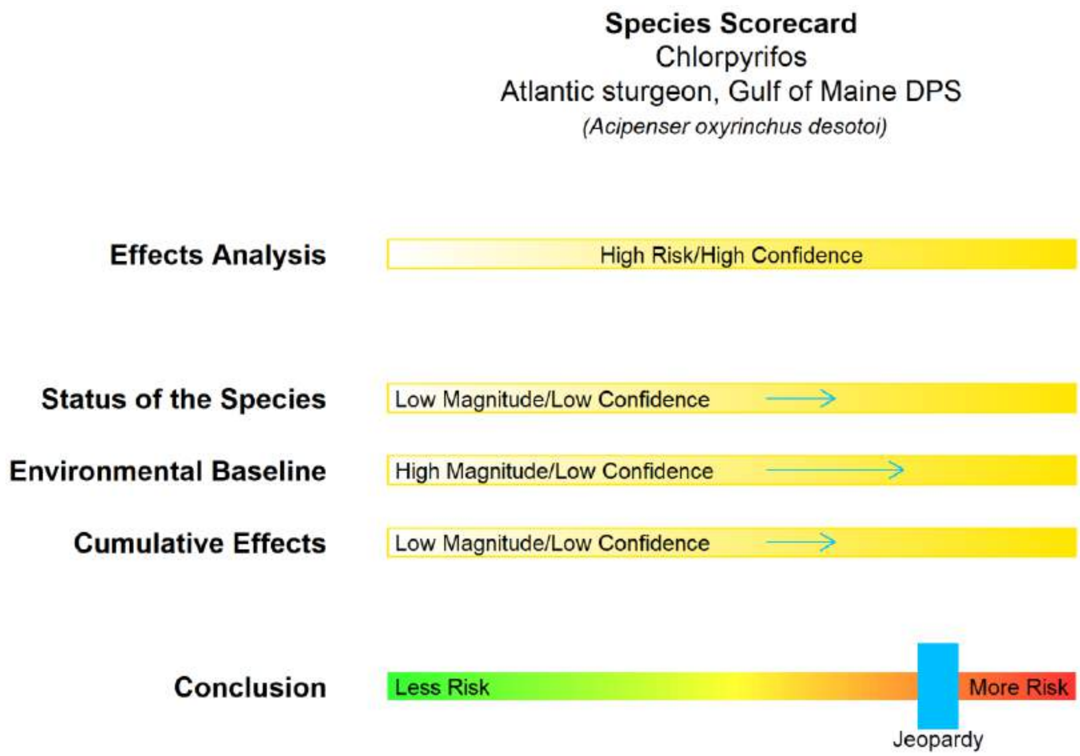

Figure 37. Species Score Card; Atlantic sturgeon, Gulf of Maine DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: minimal increased risk of jeopardy; Low magnitude/ low confidence

- 10% of historical abundance, unknown population growth rate, range expanding
- Threatened;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

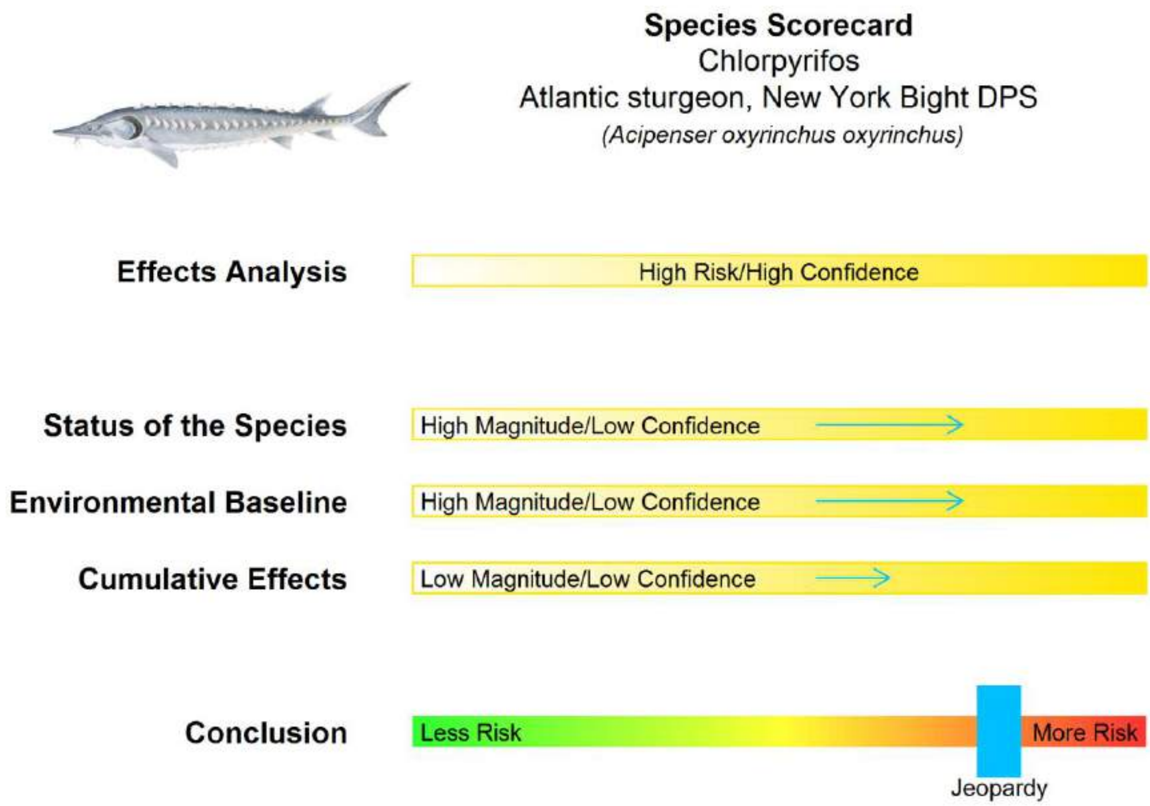

Figure 38. Species Score Card; Atlantic sturgeon, New York Bight DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence

- 4% of historical abundance, unknown population growth rate
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

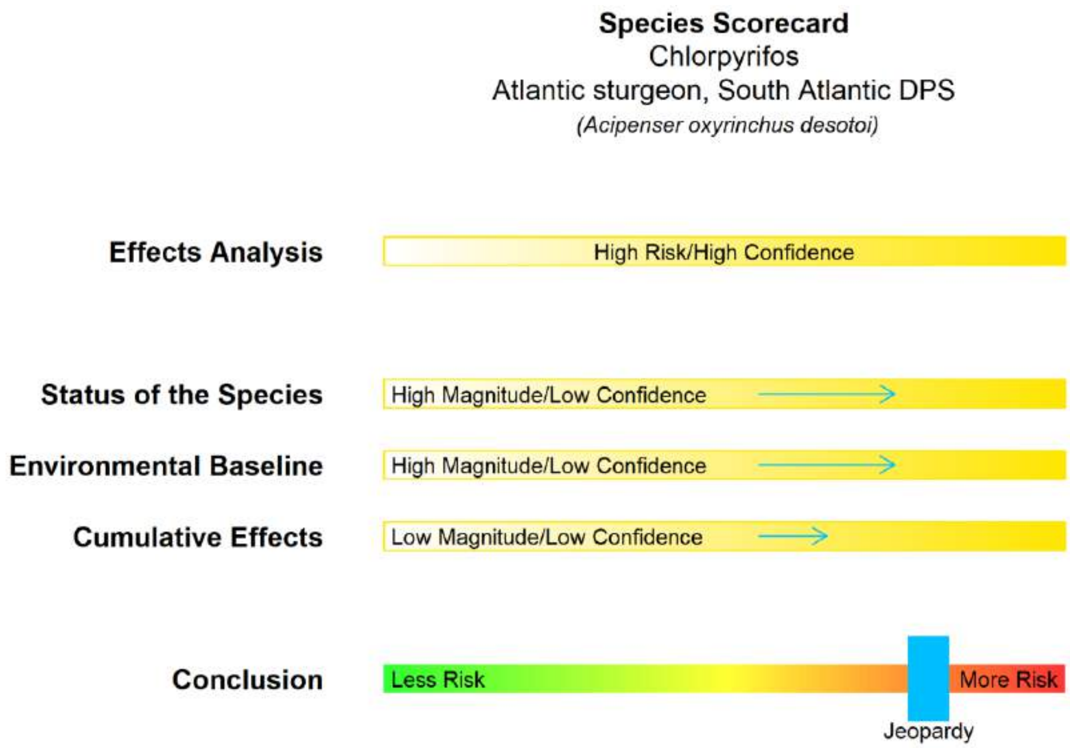

Figure 39. Species Score Card; Atlantic sturgeon, South Atlantic DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence</u>

- <6% of historical abundance
- Endangered;
- Recovery criteria not identified

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

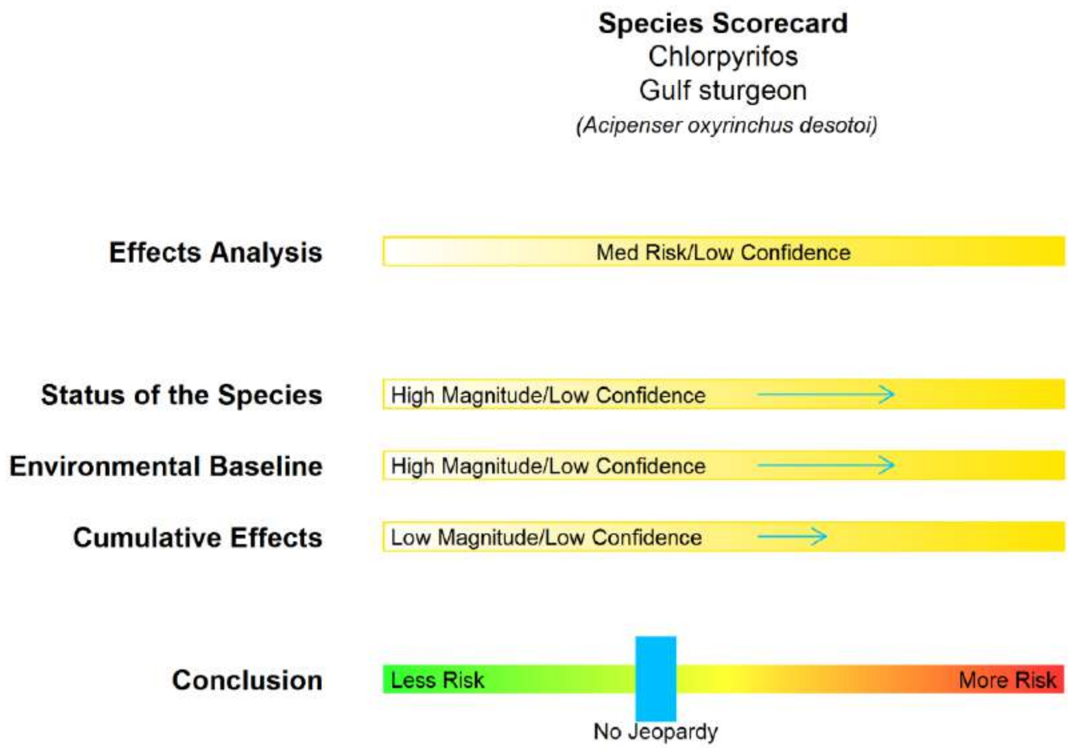

Figure 40. Species Score Card; Gulf sturgeon; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance may occur in estuarine areas
- Potential effects include death, reduced cholinesterase activity, reduced growth and prey abundance, and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Eastern range populations stable to increasing, western population lower abundances and more uncertainty, minimal growth rate data
- Threatened;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated to affect species
- Anticipated hydrologic effects in freshwater areas

Conclusion: In estuarine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in these estuarine areas where they rear. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

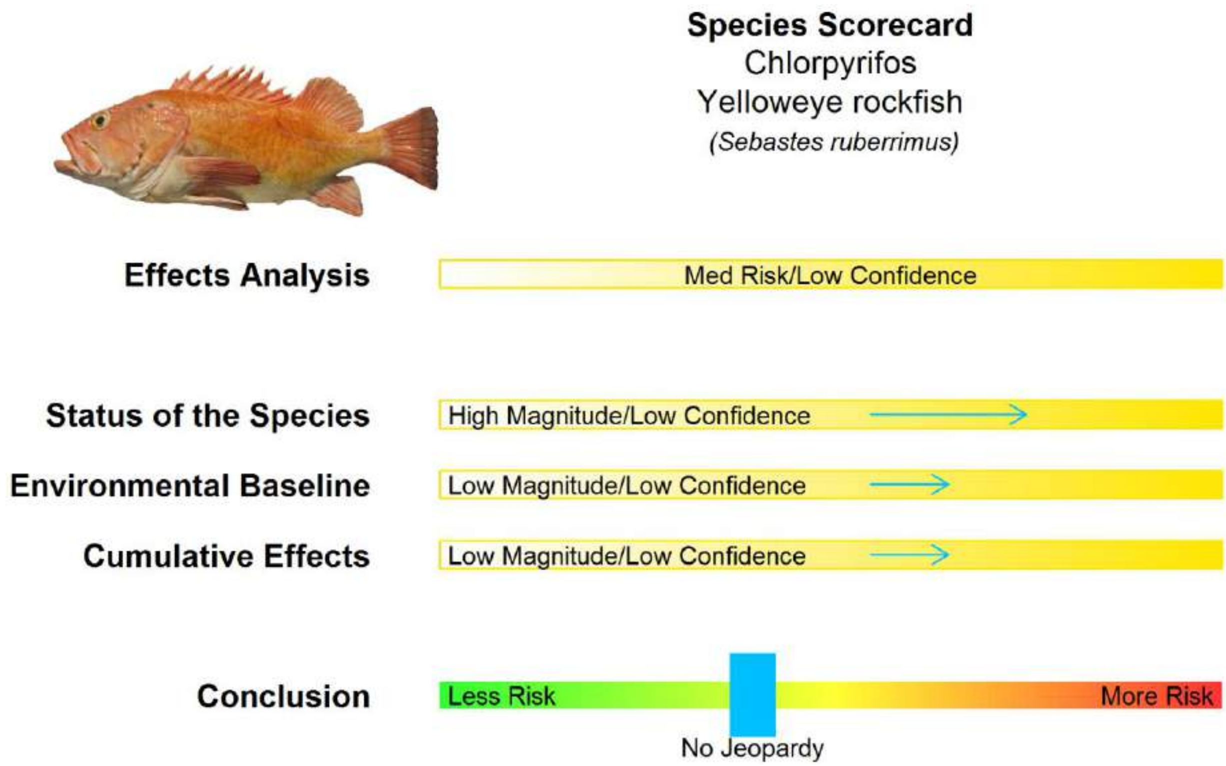

Figure 41. Species Score Card; Yelloweye rockfish; Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance may occur in marine areas
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Historically low abundance, fragmented populations, altered population age structure
- Threatened;
- Recovery criteria not identified

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures at toxic concentrations unanticipated in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations and species use of deep water habitats. The species is most at risk while in shallow surface, marine areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

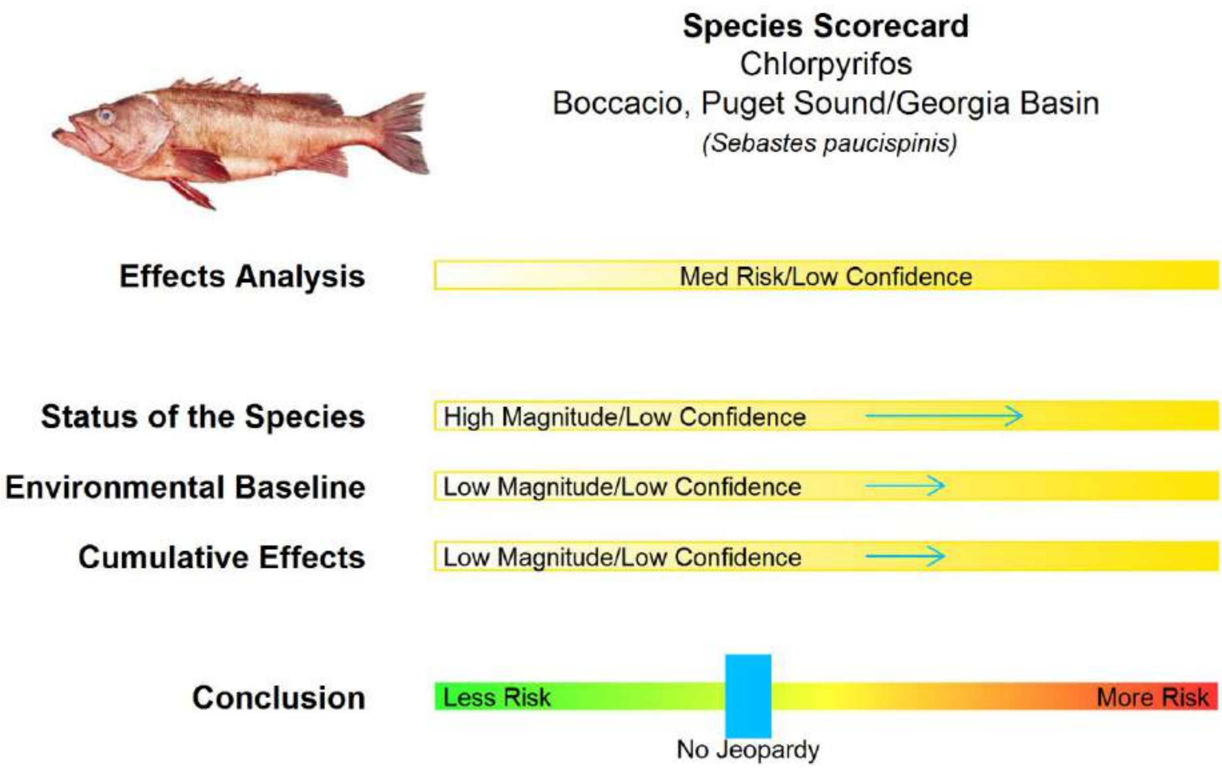

Figure 42. Species Score Card; Boccacio, Puget Sound/Georgia Basin; Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance may occur in marine areas
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- There are no estimates of historical or current abundance across the DPS's full range; Indices suggest declining abundance trends
- Threatened;
- Recovery criteria not identified

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas where they rear. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

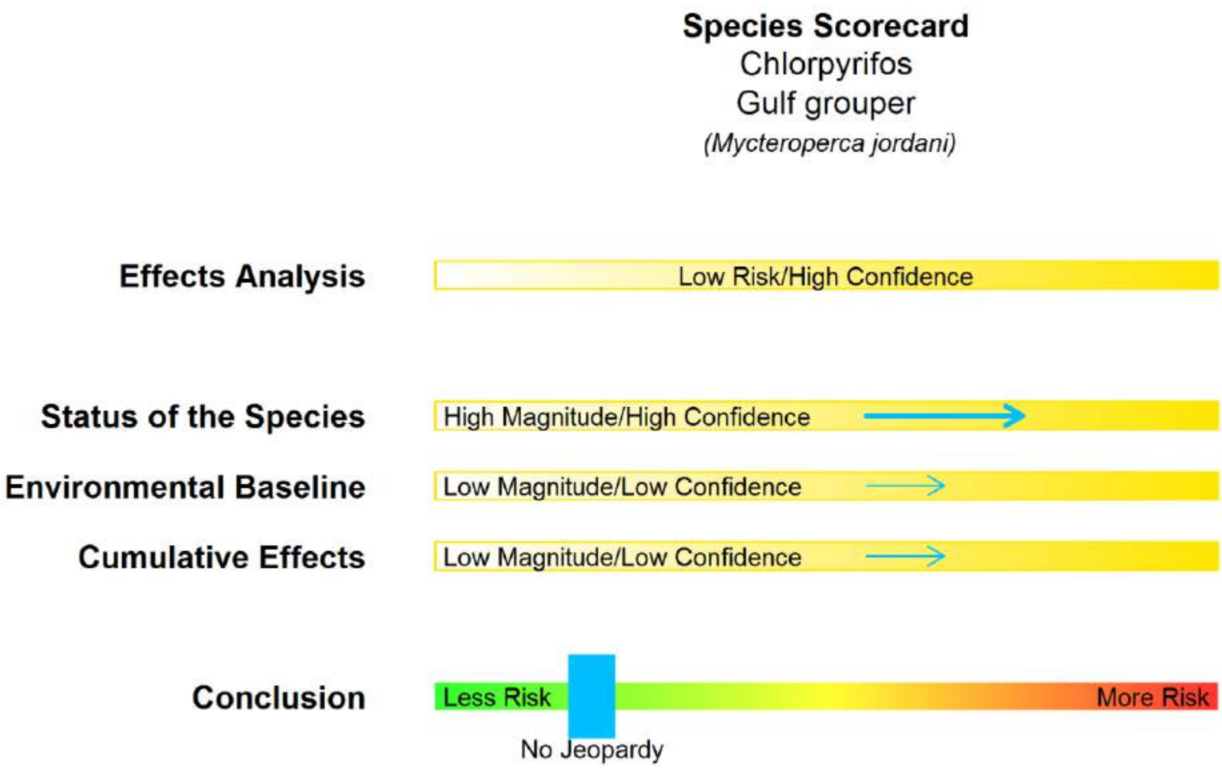

Figure 43. Species Score Card; Gulf grouper; Chlorpyrifos

<u>Effects Analysis: Low risk/High confidence</u>

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Abundance levels less than 1% of their historical levels
- Endangered;
- Recovery criteria not identified

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

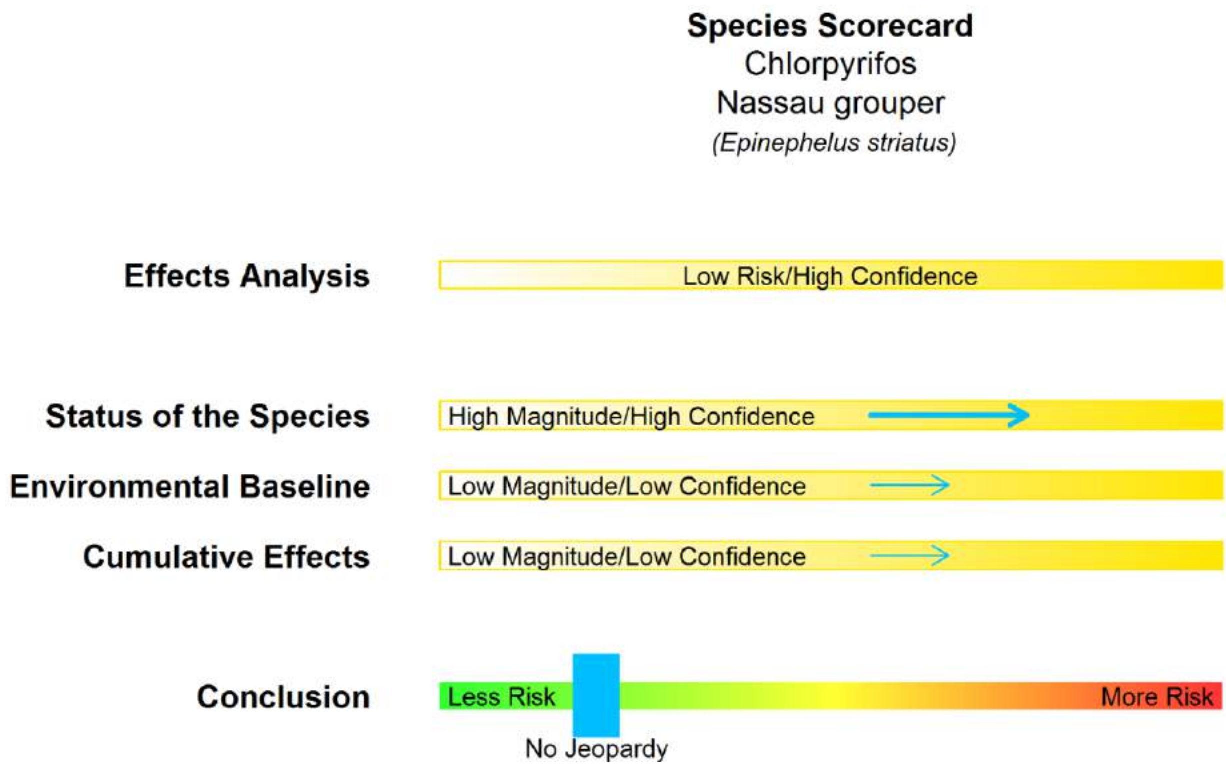

Figure 44. Species Score Card; Nassau grouper; Chlorpyrifos

Effects Analysis: Low risk/High confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- The species has pathcy abundance with declining abundance trends. Throughout its range reductions in the size and number of spawning aggregations;
- Threatened;
- Recovery criteria not identified

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures not anticipated at toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

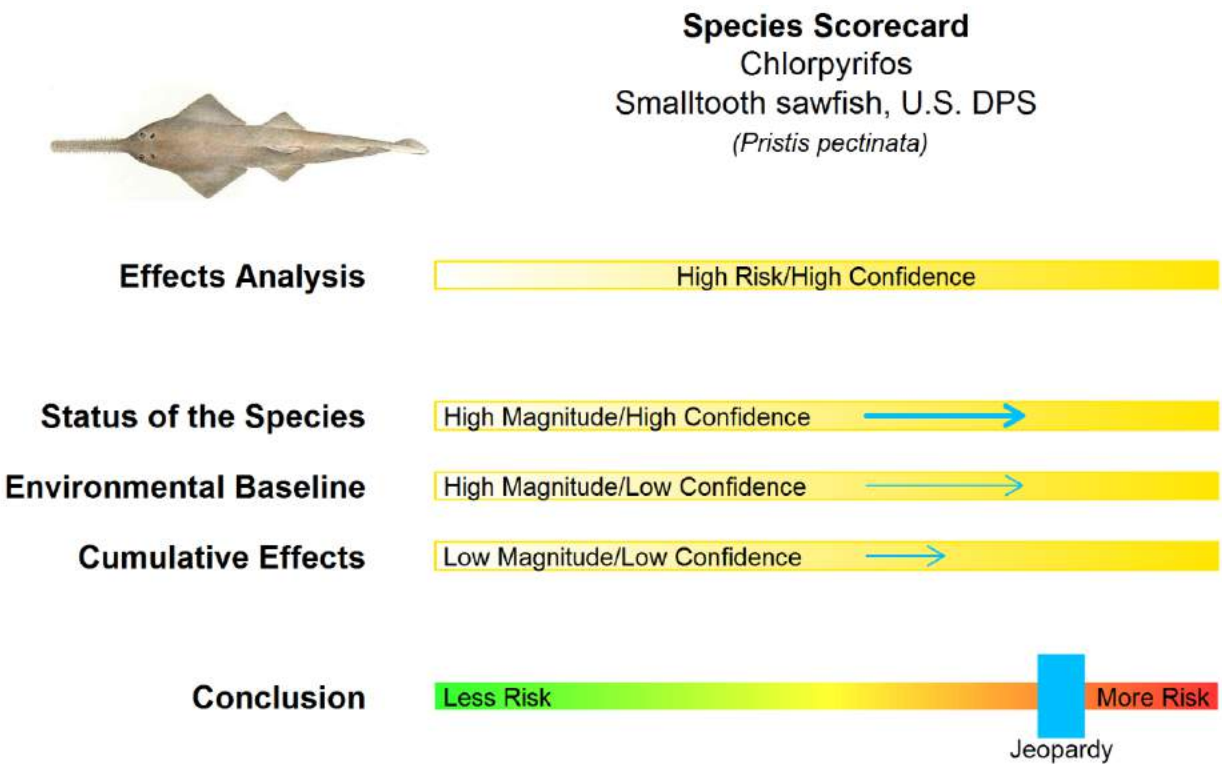

Figure 45. Species Score Card; Smalltooth sawfish, U.S. DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and estuarine areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Stable abundance, low population growth rates, <5% of historical abundance
- Endangered;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

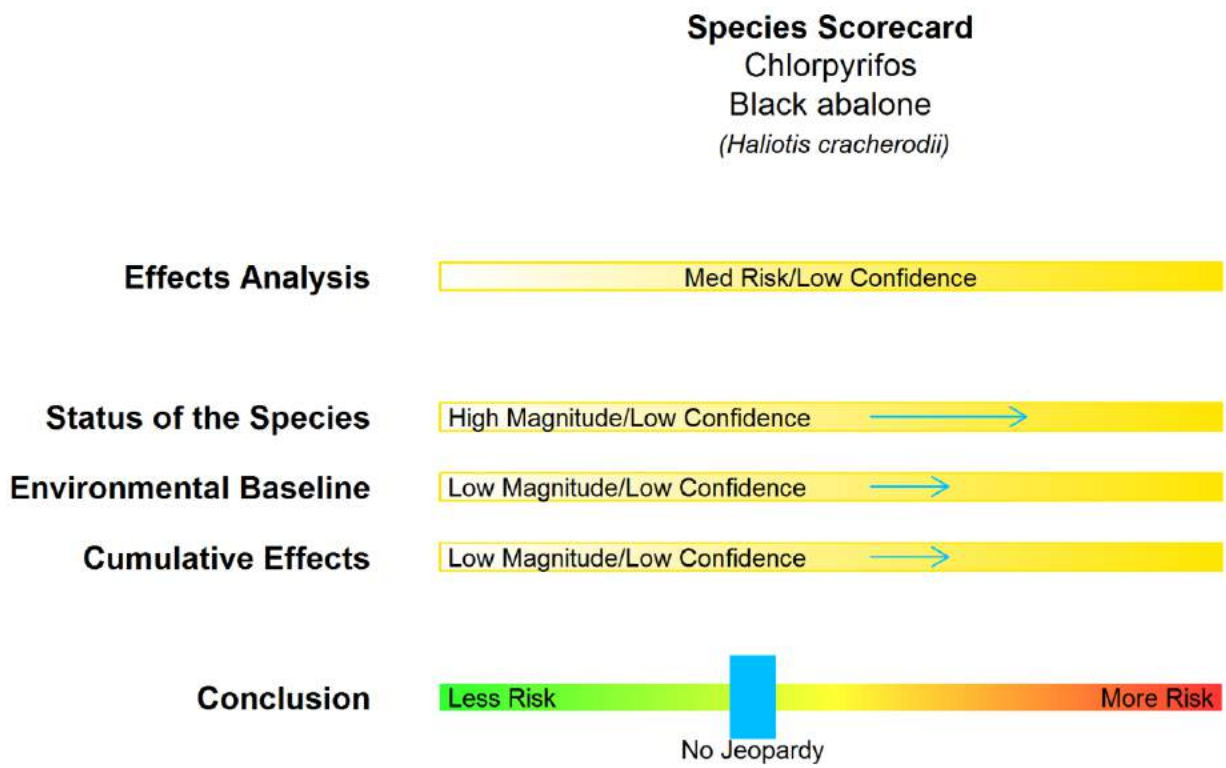

Figure 46. Species Score Card; Black abalone; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance may occur in marine areas
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- 5% of historical abundance, declining population trend
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in the surface areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

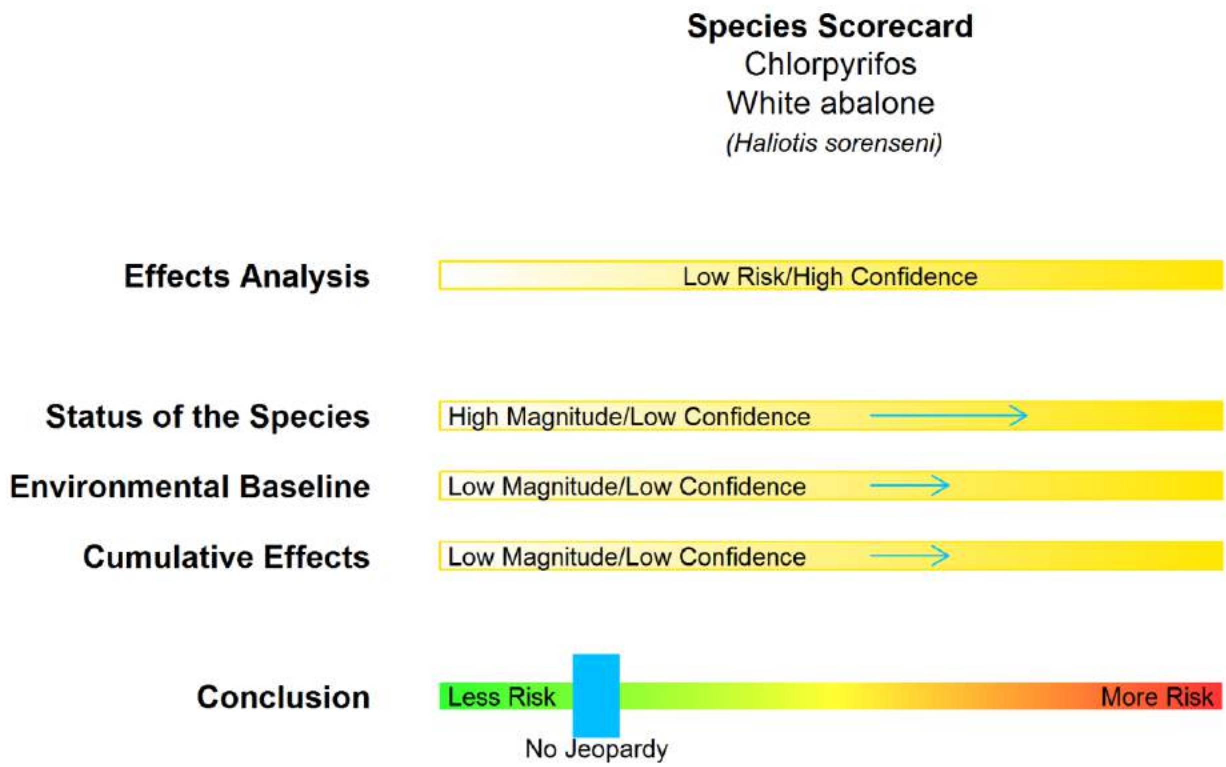

Figure 47. Species Score Card; White abalone; Chlorpyrifos

Effects Analysis: Low risk/High confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some individual include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Declining population trend, lack of recruitment, no current estimated population size
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on high confidence in minimal exposure to the stressor of the action. The species is most at risk while in the surface areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

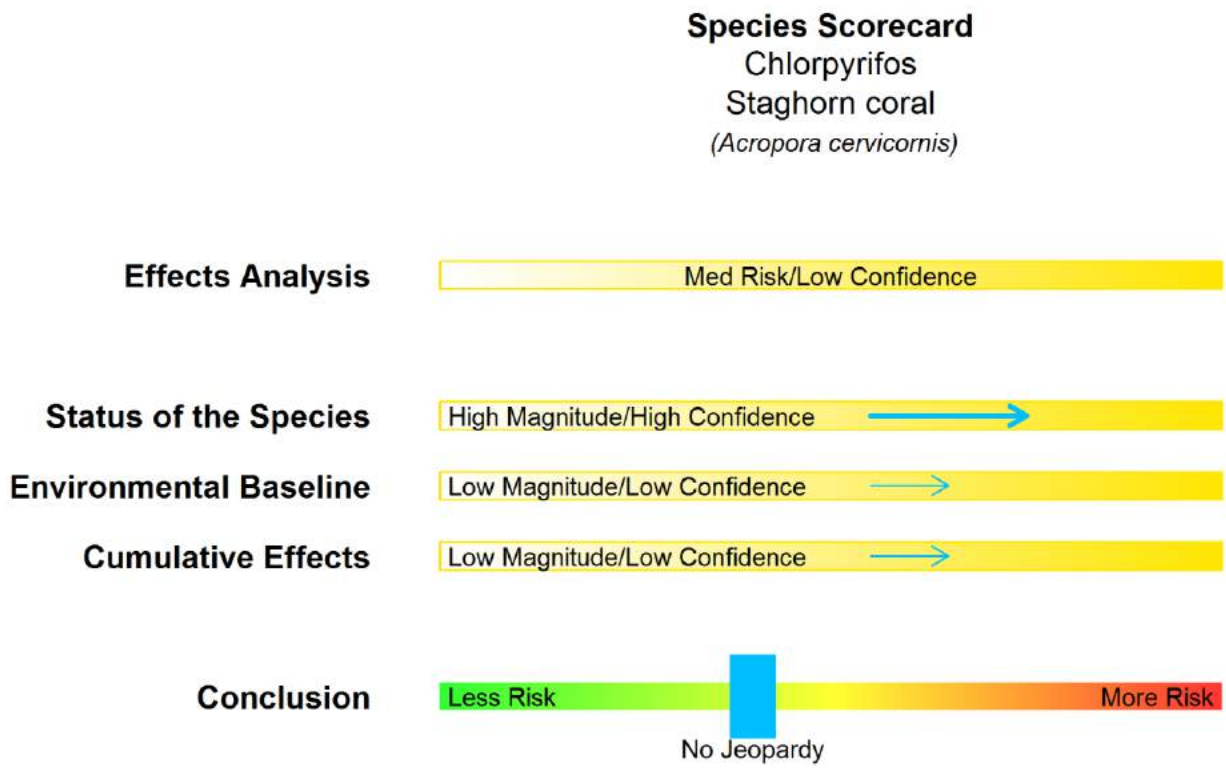

Figure 48. Species Score Card; Staghorn coral; Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Severe reductions in abundance in portions of range. Populations remain stable at depressed levels;
- Threatened;
- Recovery criteria not met.

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on high confidence in minimal exposure to the stressor of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

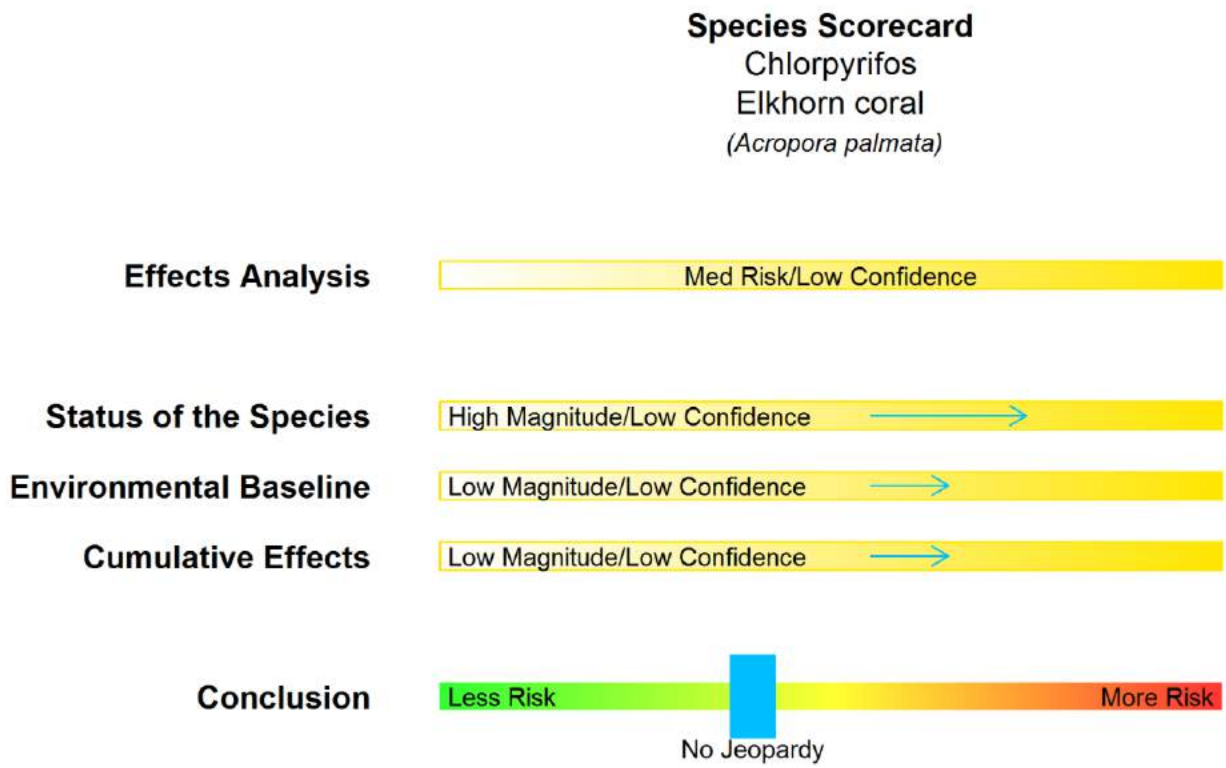

Figure 49. Species Score Card; Elkhorn coral; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Low abundance, large declines over past decades. Genetically depauparate populations in Caribbean. In eastern Caribbean, population is doing better and is genetically richer.
- Threatened;
- Recovery criteria not met.

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on high confidence in minimal exposure to the stressor of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

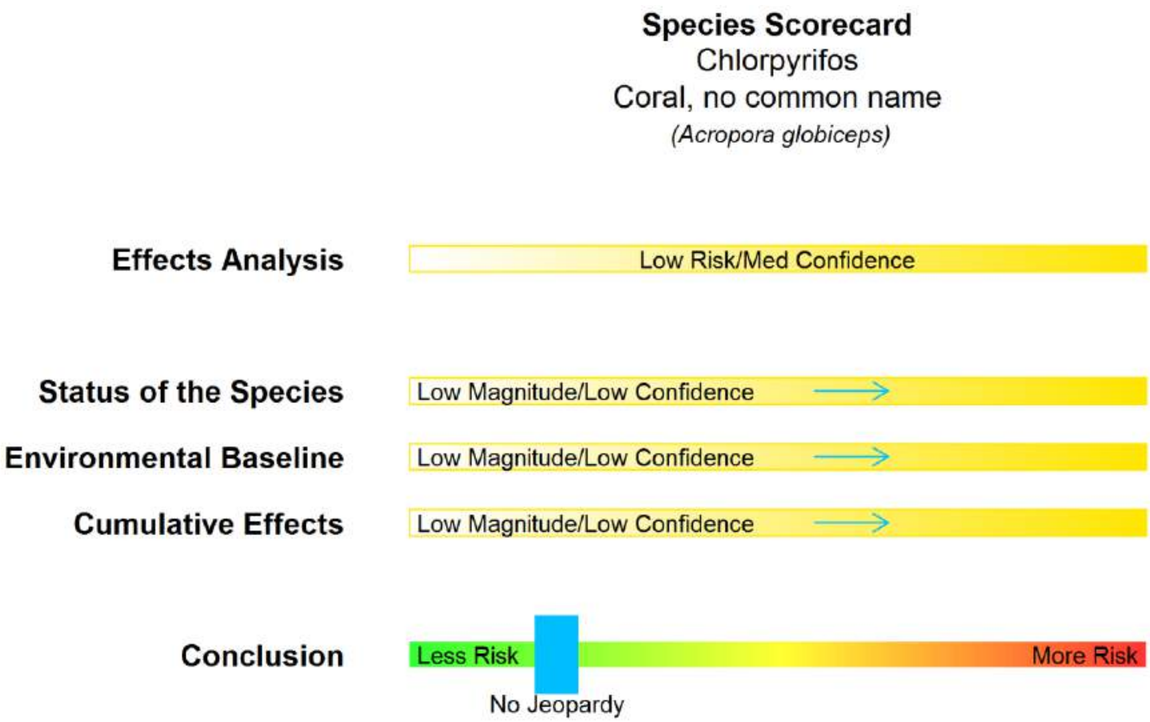

Figure 50. Species Score Card; Coral, Acropora globiceps; Chlorpyrifos

Effects Analysis: Low risk/Medium confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

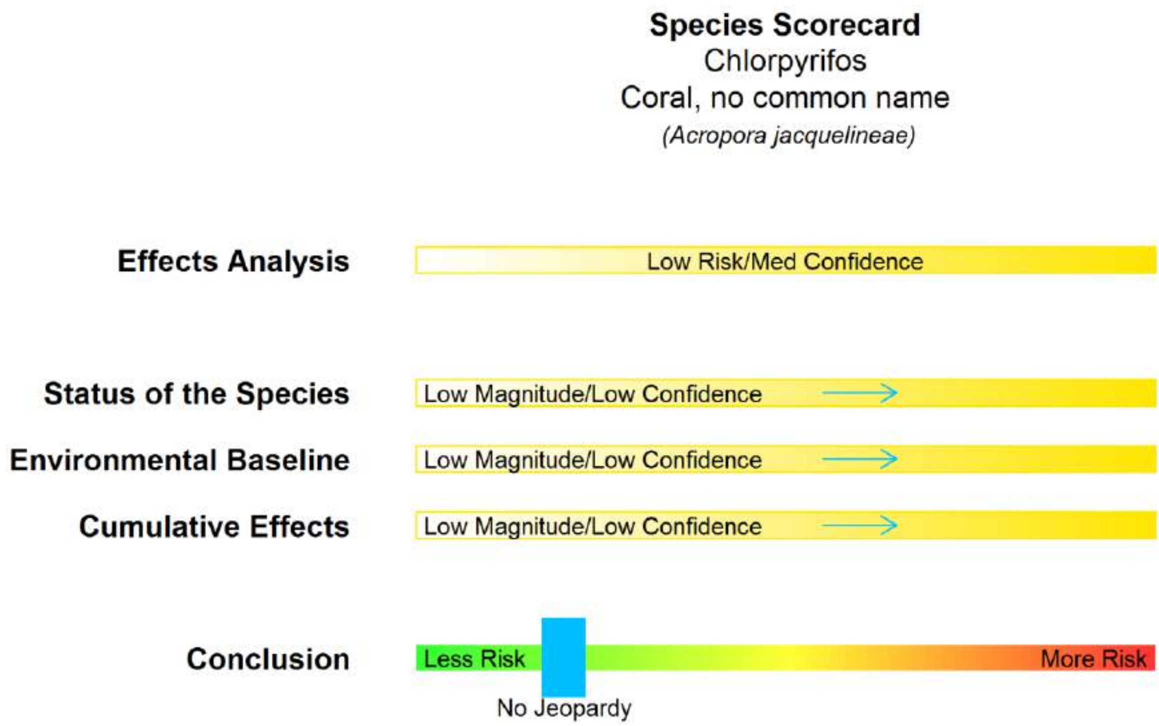

Figure 51. Species Score Card; Coral, Acropora jacquelineae; Chlorpyrifos

Effects Analysis: Low risk/Medium confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

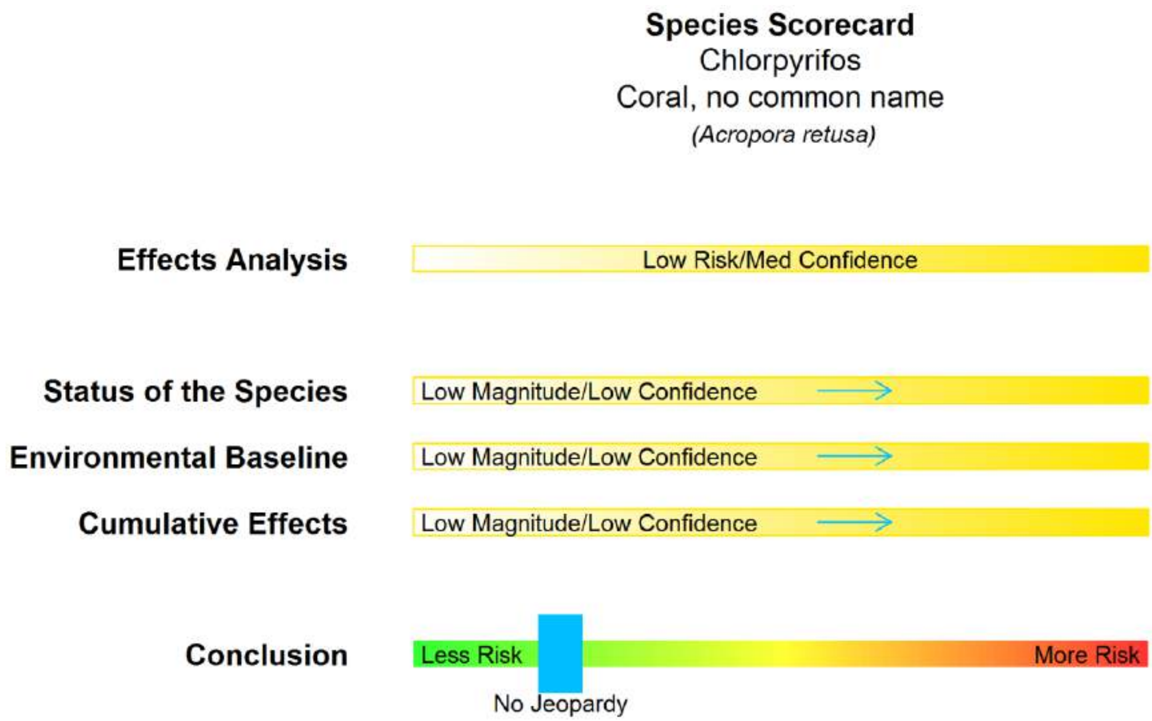

Figure 52. Species Score Card; Coral, Acropora retusa; Chlorpyrifos

Effects Analysis: Low risk/Medium confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

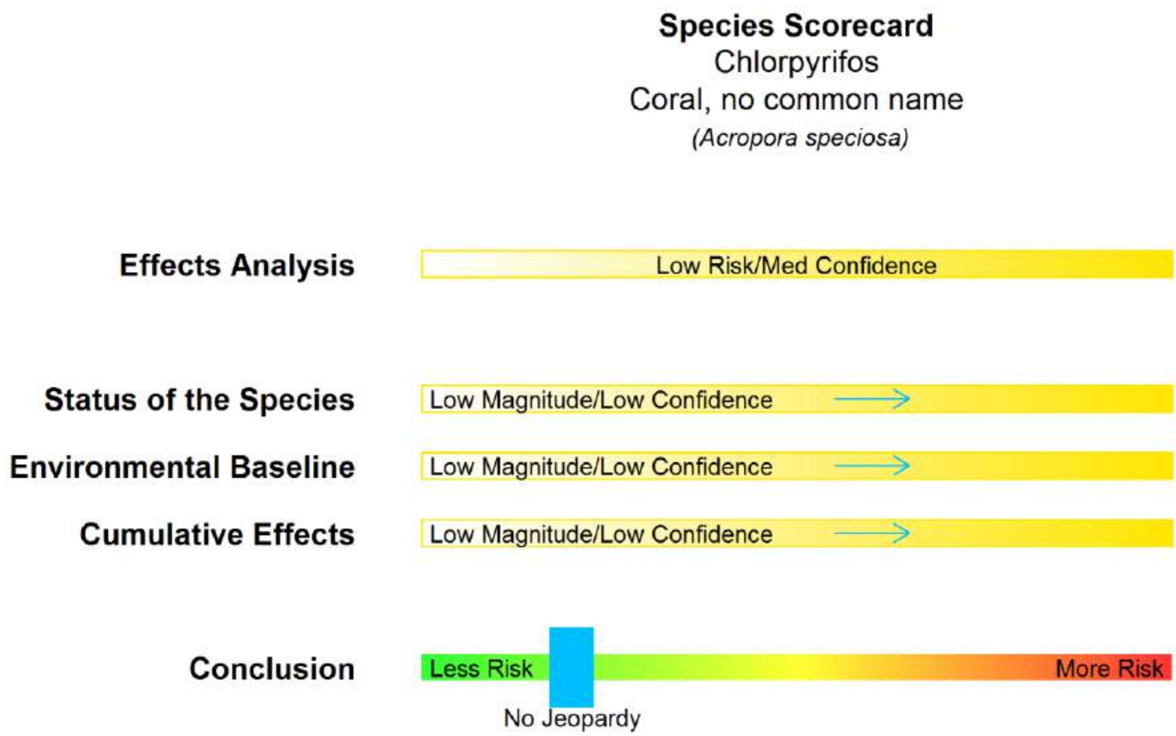

Figure 53. Species Score Card; Coral, Acropora speciosa; Chlorpyrifos

<u>Effects Analysis: Low risk/Medium confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

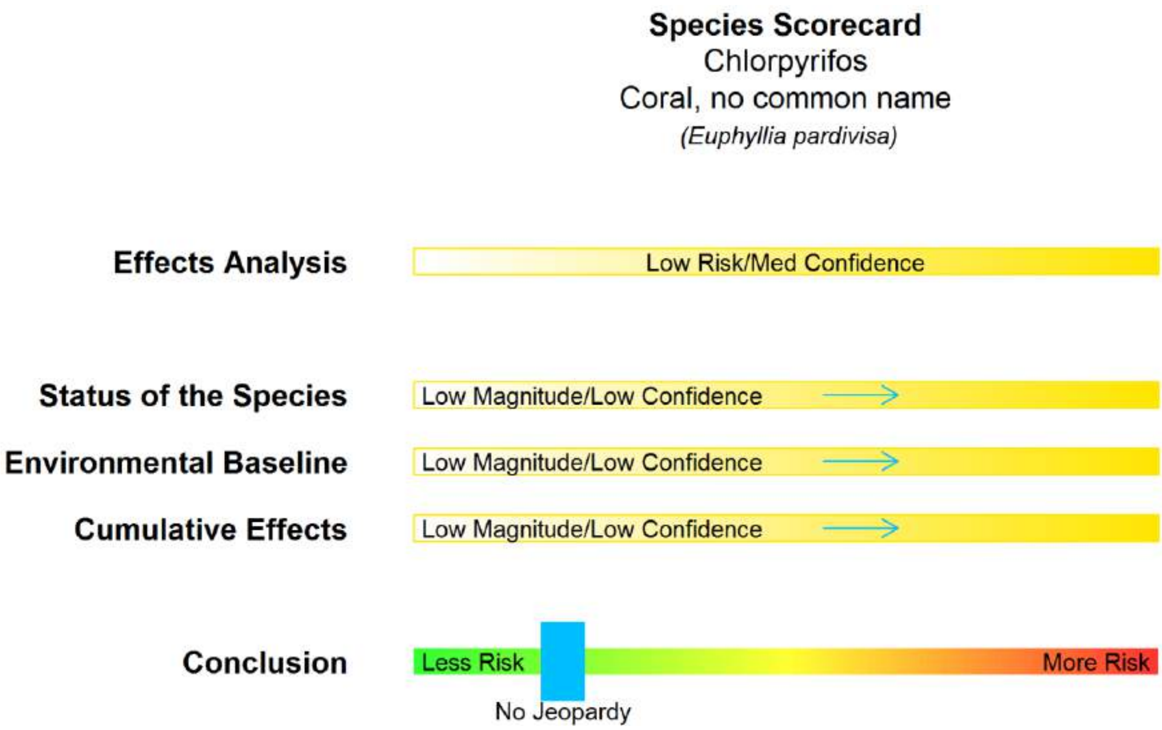

Figure 54. Species Score Card; Coral, Euphyllia pardivisa; Chlorpyrifos

Effects Analysis: Low risk/Medium confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

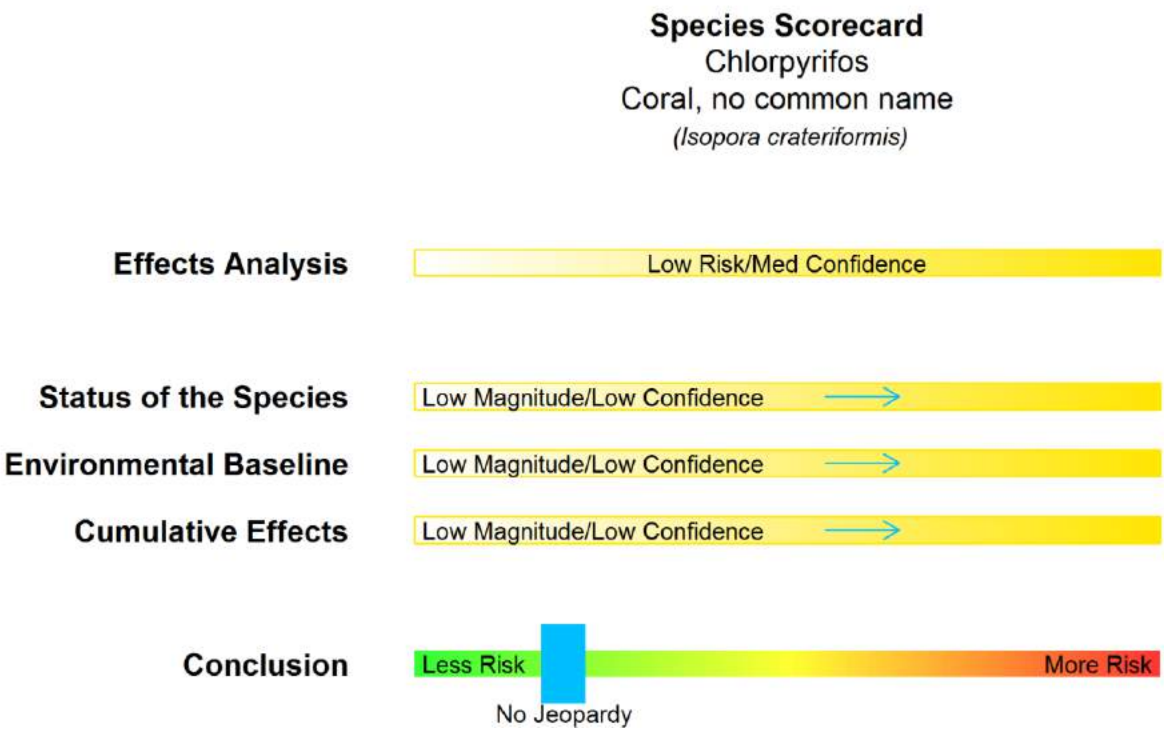

Figure 55. Species Score Card; Coral, Isopora crateriformis; Chlorpyrifos

Effects Analysis: Low risk/Medium confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

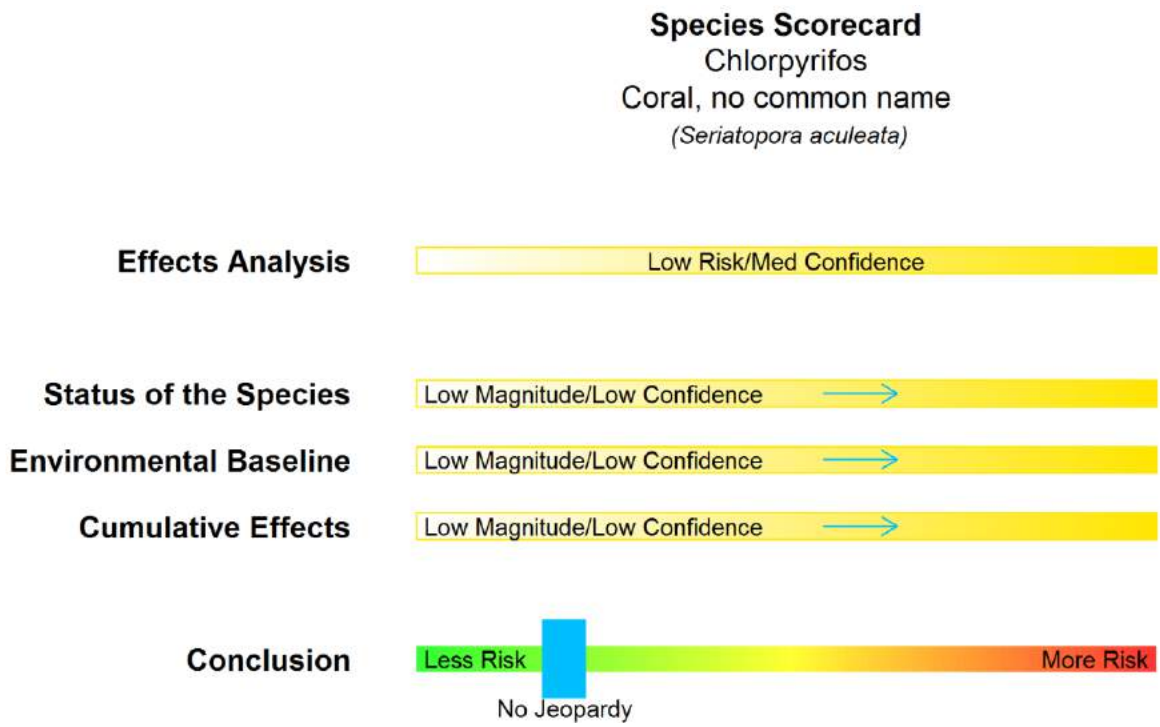

Figure 56. Species Score Card; Coral, Seriatopora aculeata; Chlorpyrifos

Effects Analysis: Low risk/Medium confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

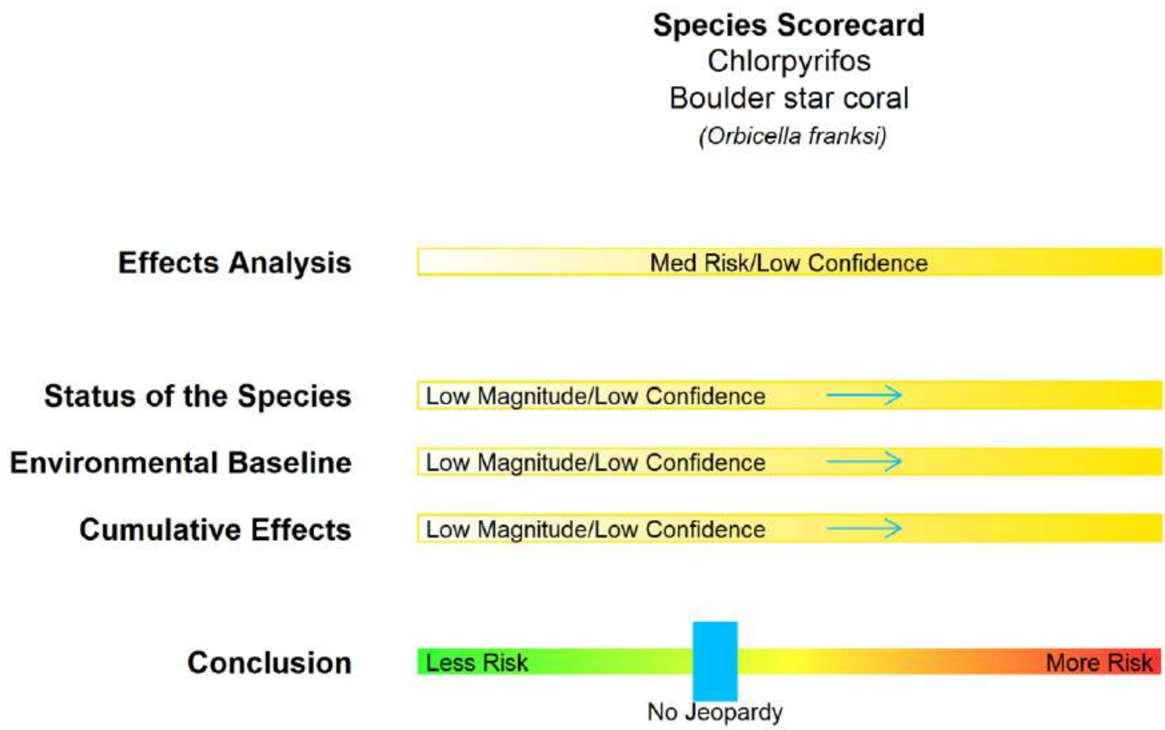

Figure 57. Species Score Card; Boulder star coral; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Reductions in abundance, population is currently stable
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

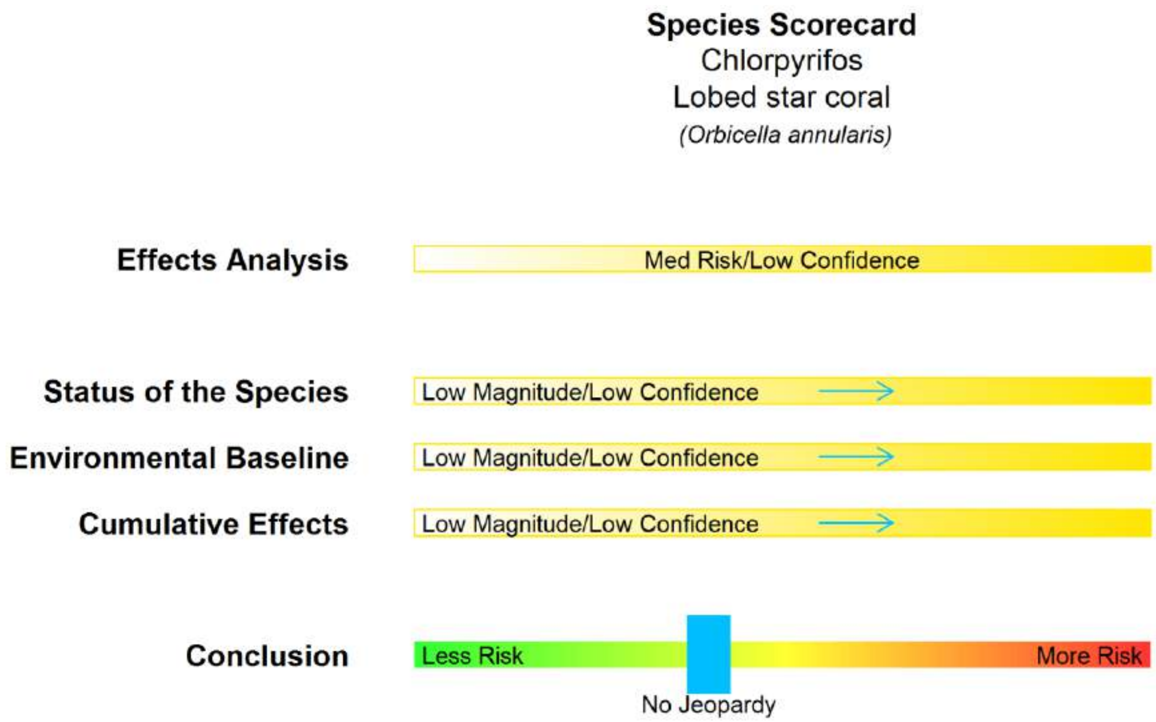

Figure 58. Species Score Card; Lobed star coral; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- 60% decline 2001-2012 due to bleaching. Most were considered "partial" mortalities to the colony. Abundance is stable.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

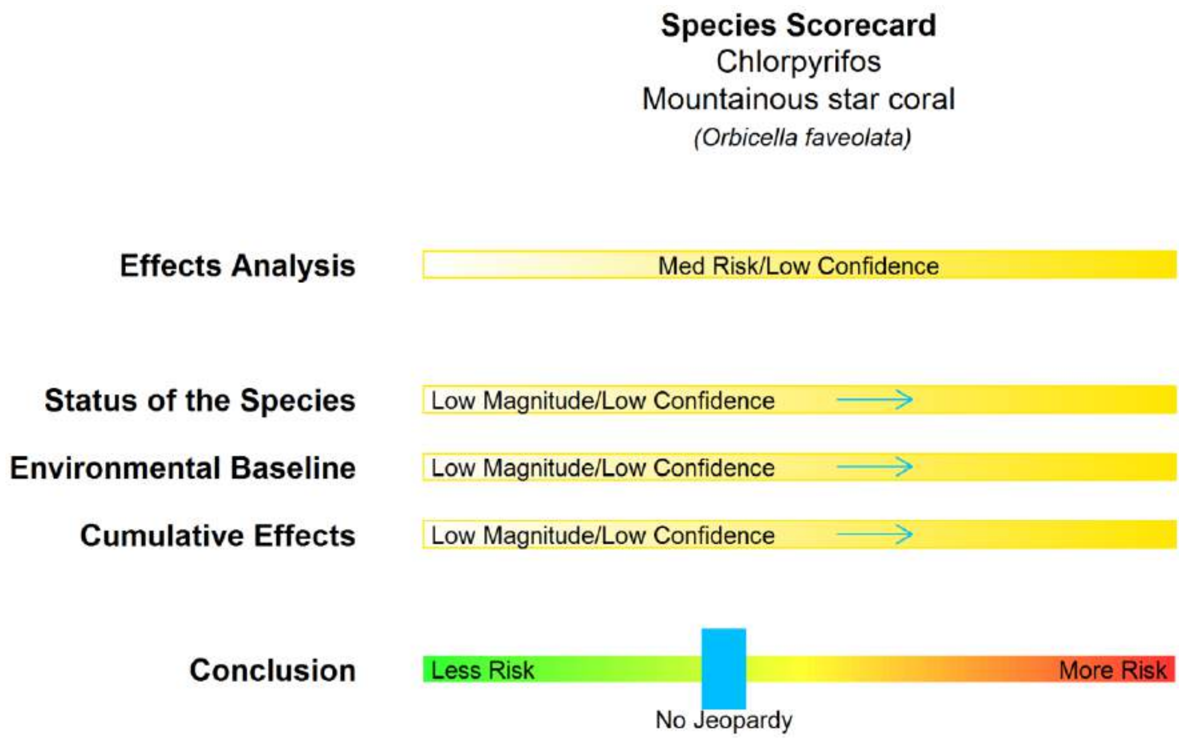

Figure 59. Species Score Card; Mountainous star coral; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Some areas have shown major declines due to warming induced bleaching and disease; however this species is considered abundant.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

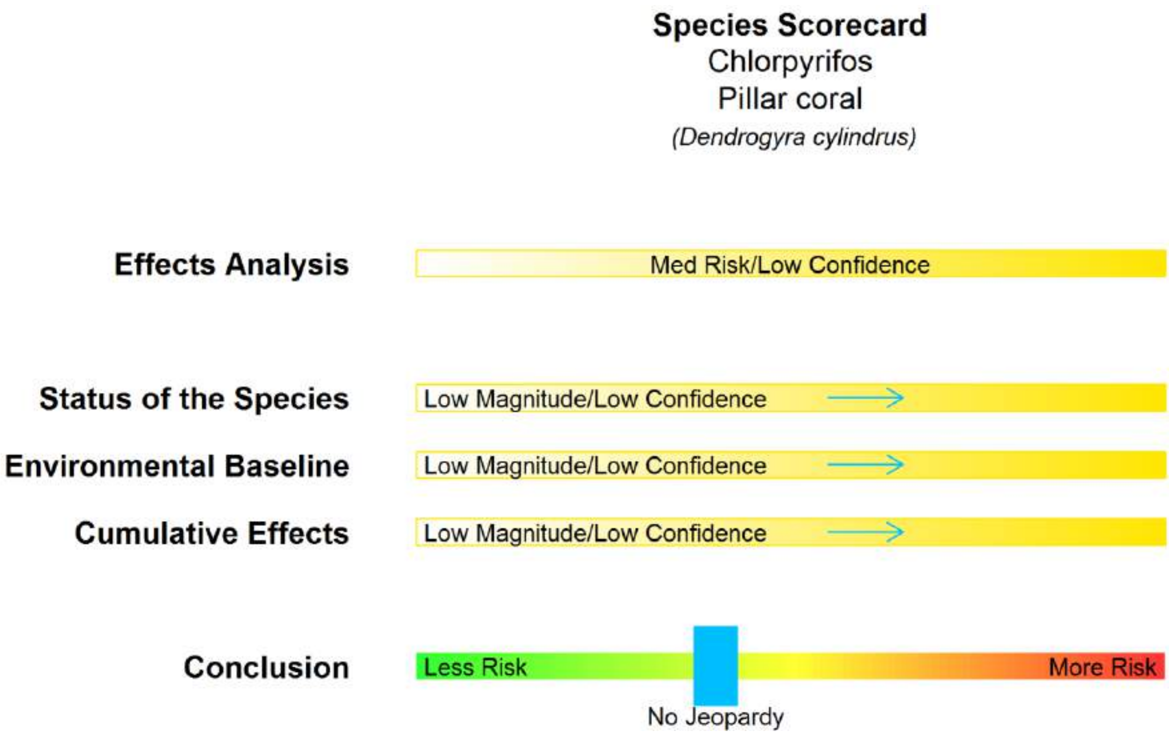

Figure 60. Species Score Card; Pillar coral; Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Uncommon, rarely found in aggregations - yet little evidence of population declines over years of monitoring. Unknown trends in abundance or productivity
- Threatened;
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

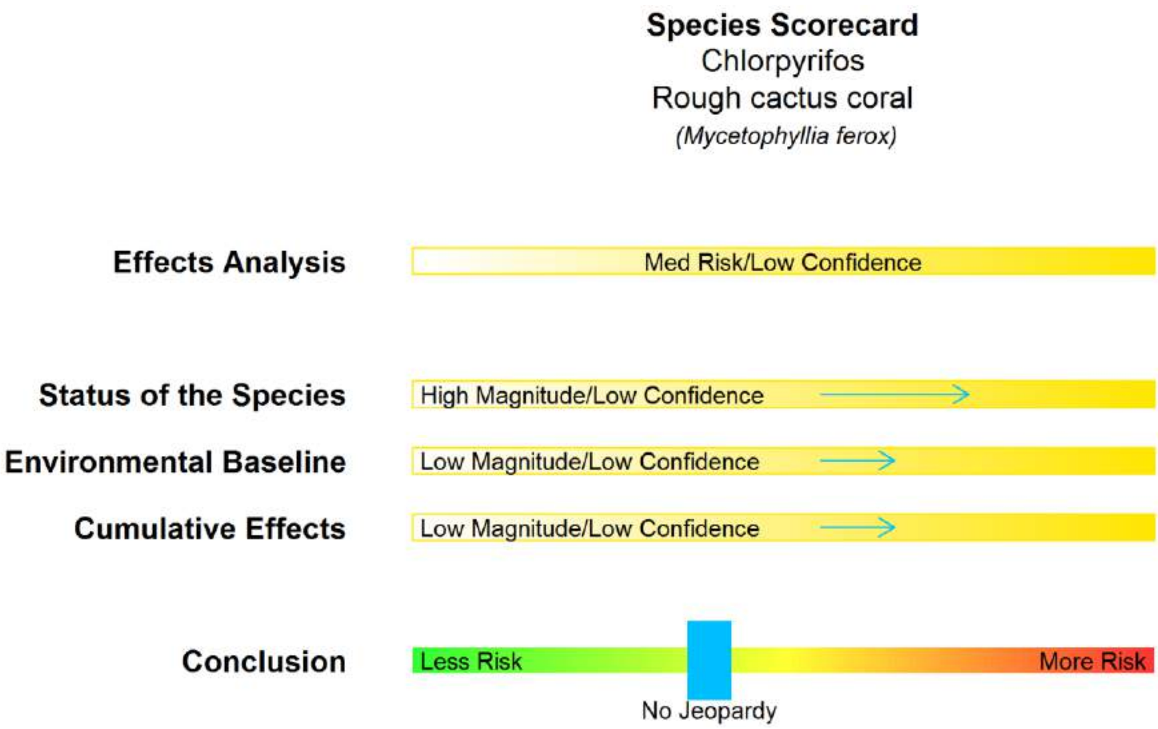

Figure 61. Species Score Card; Rough cactus coral; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Uncommon to rare. Species saw declines since the 1970's. Highly affected by disease. Unknown trends in abundance or productivity
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

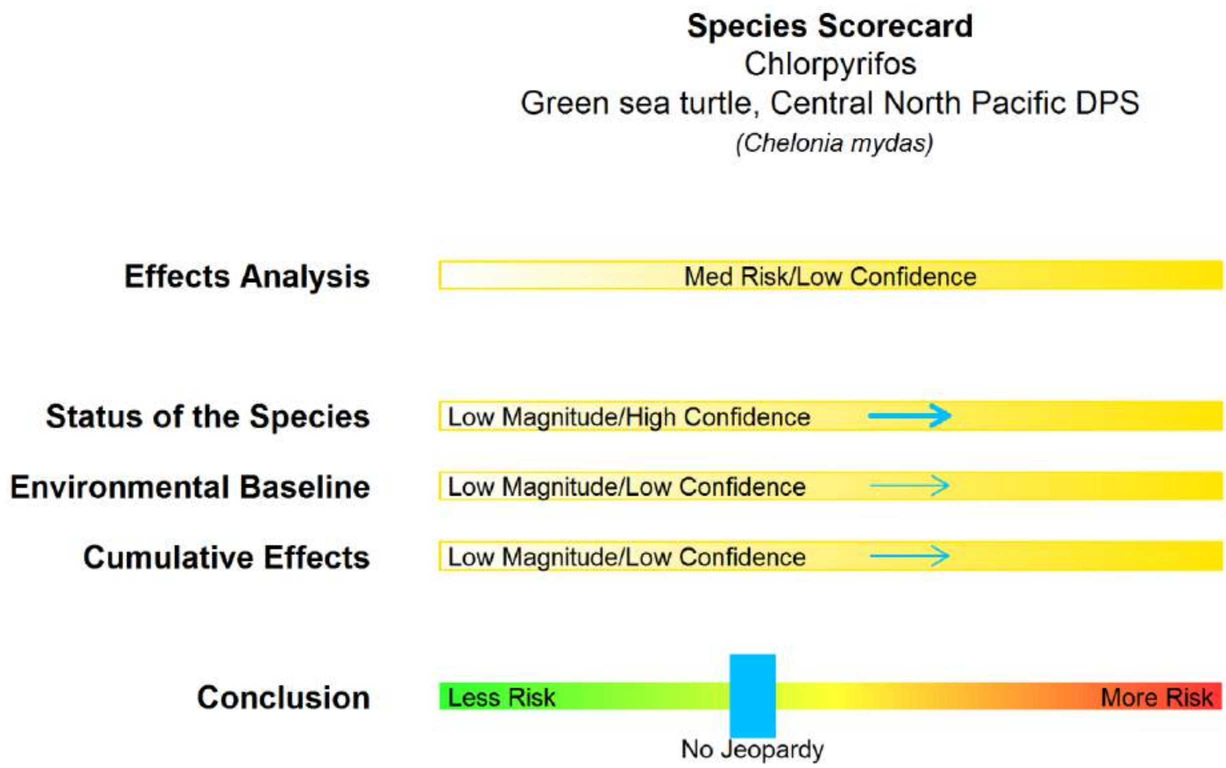

Figure 62. Species Score Card; Green sea turtle, Central North Pacific DPS; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- Population nesting abundance is increasing at estimated rate of 4.8% annually. DPS has low level of genetic diversity. Population considered resilient.
- Threatened;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

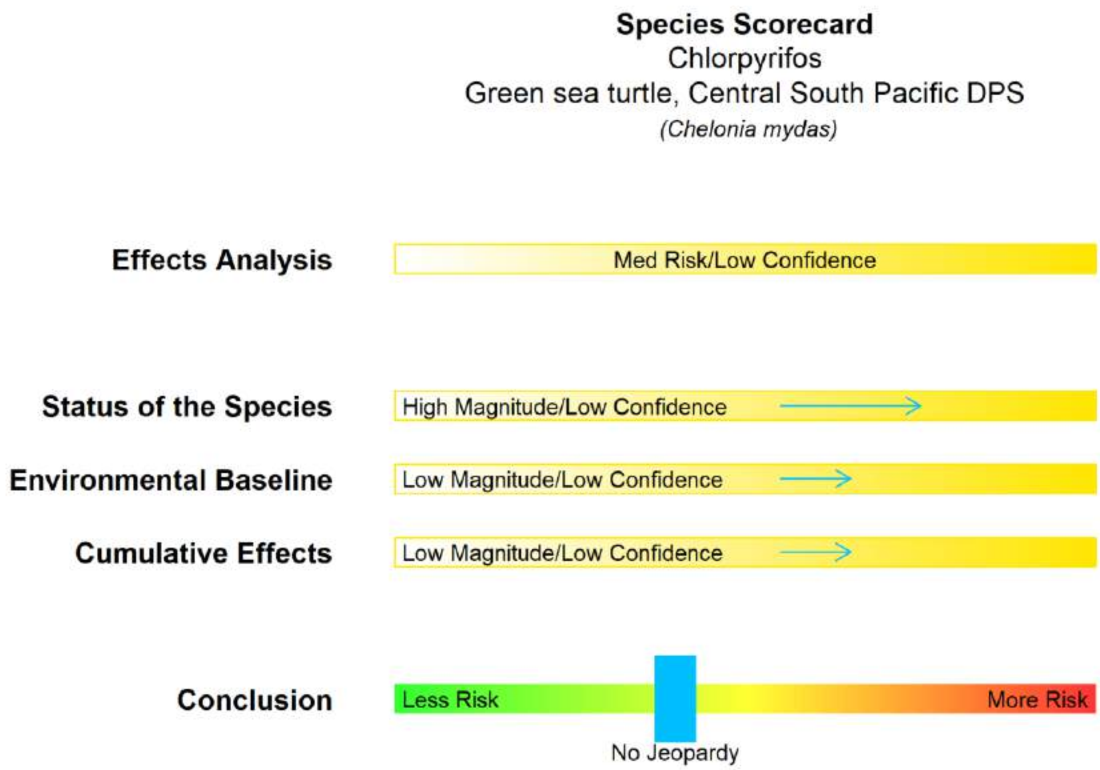

Figure 63. Species Score Card; Green sea turtle, Central South Pacific DPS; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Nesting abundance considered low, 59 known sites; Unknown population trends; Existing data suggest steep declines due to illegal harvest of eggs. Nesting areas typically outside of the action area (US, territories, protectorates, etc.)
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

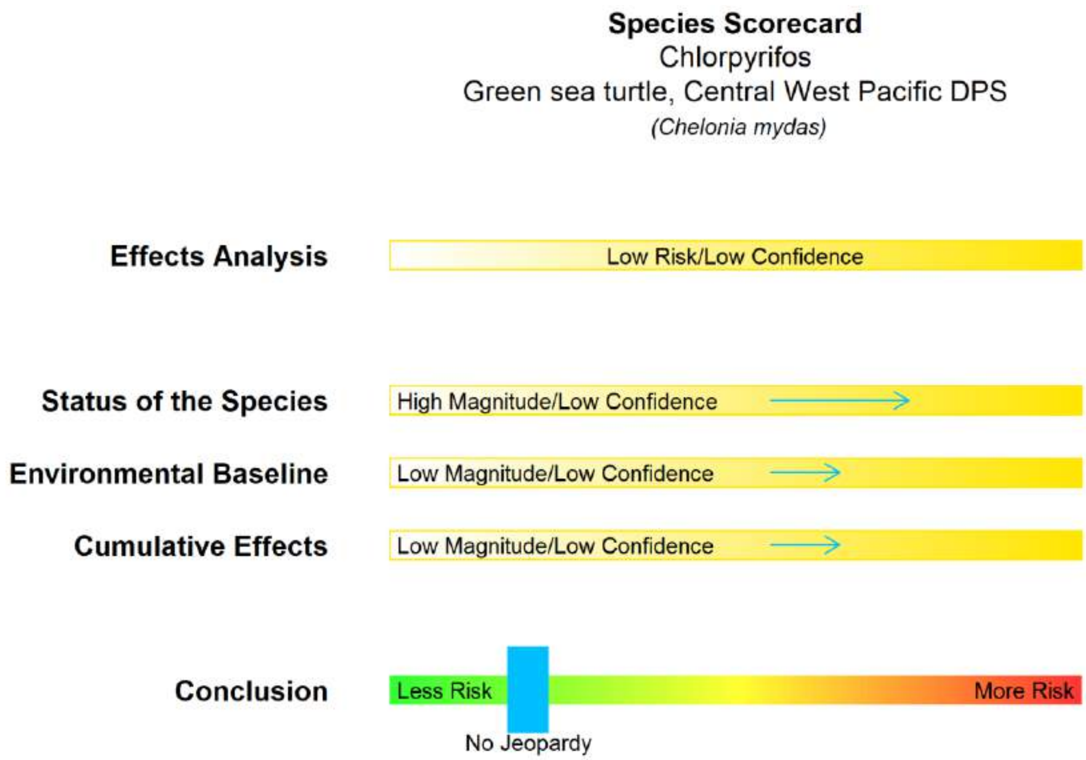

Figure 64. Species Score Card; Green sea turtle, Central West Pacific DPS; Chlorpyrifos

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- No available population trend data; Most of species' range outside of action area.
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

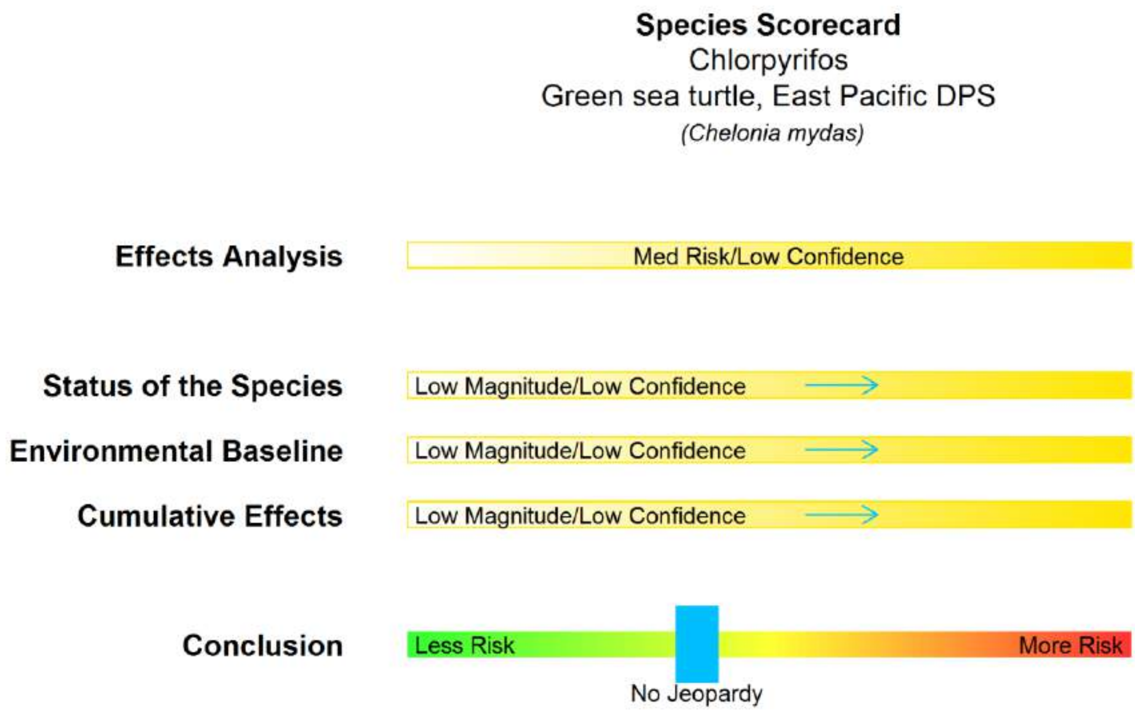

Figure 65. Species Score Card; Green sea turtle, East Pacific DPS; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- 39 nesting sites with an estimated 20,062 nesting females.; The largest nesting site is at Colola, Mexico, which hosts 58% of the nesting females for the DPS where monitoring data suggest the population is increasing.
- Threatened;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

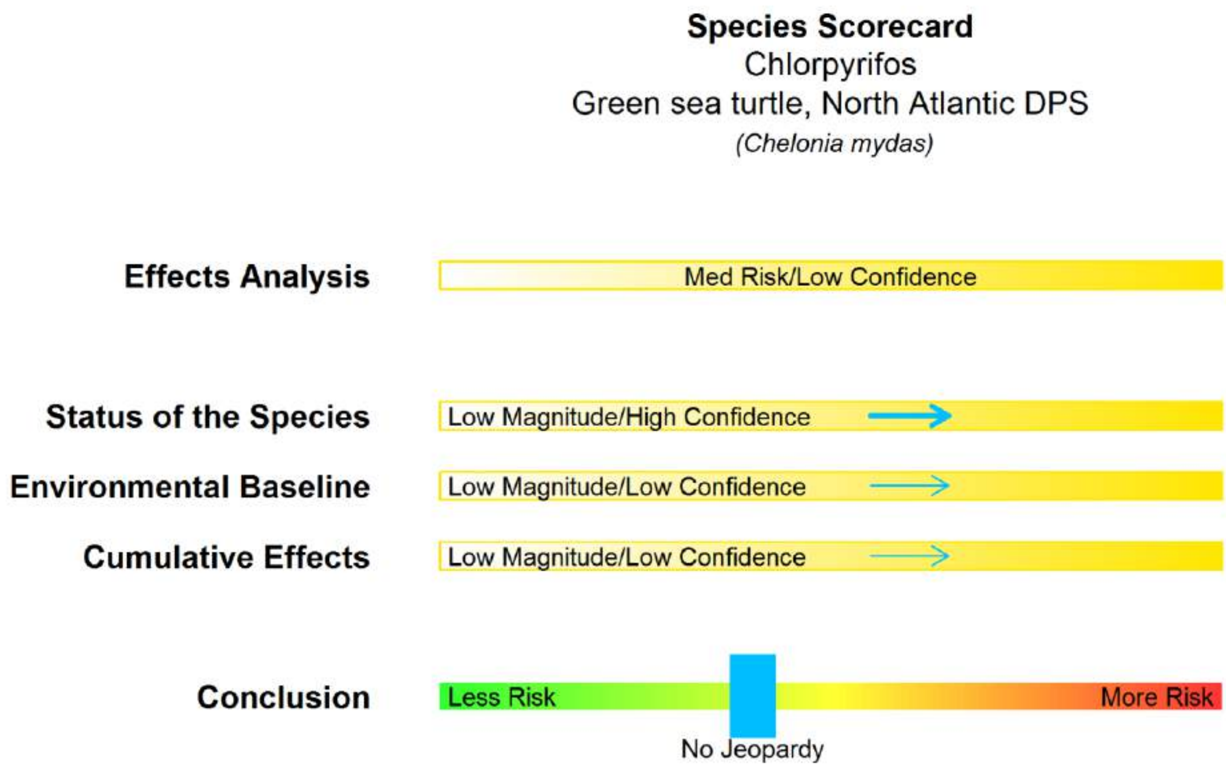

Figure 66. Species Score Card; Green sea turtle, North Atlantic DPS; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Population shows increasing trend.
- Threatened;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

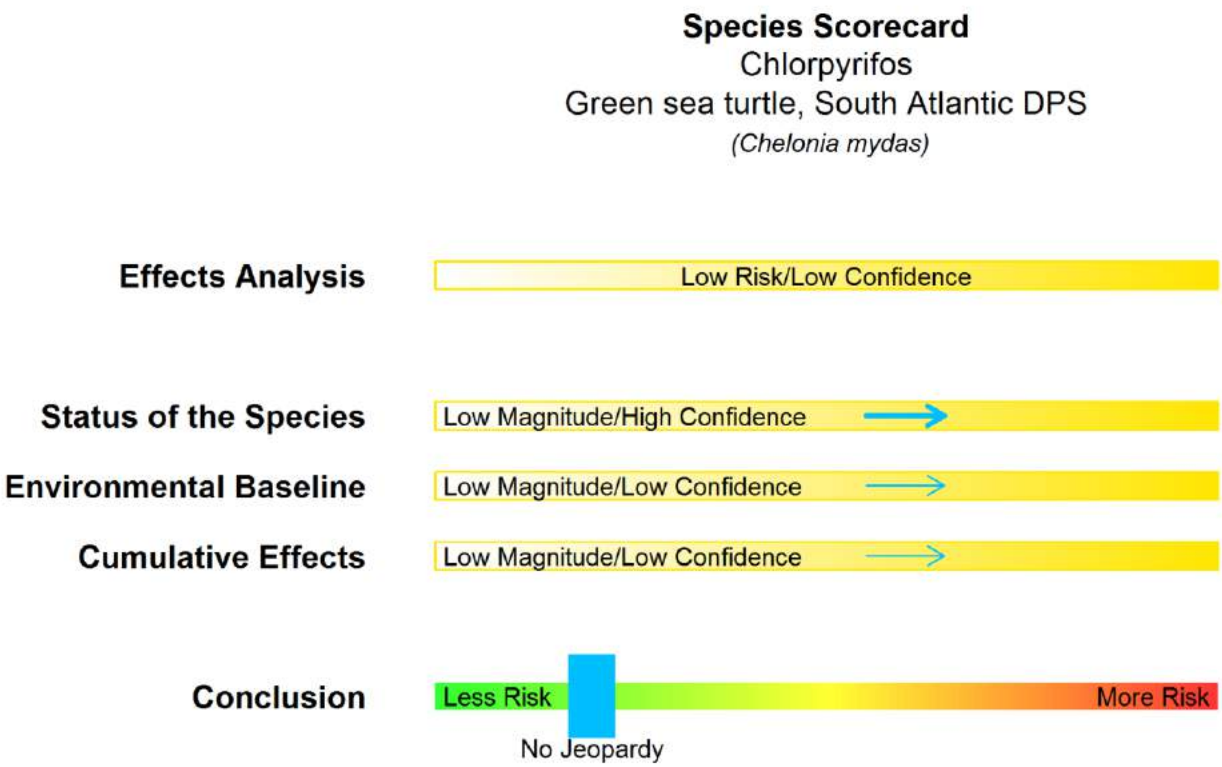

Figure 67. Species Score Card; Green sea turtle, South Atlantic DPS; Chlorpyrifos

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Sparse data available, suggests population is increasing; Most of DPS range outside of the action area;
- Threatened;
- Recovery criteria not all met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

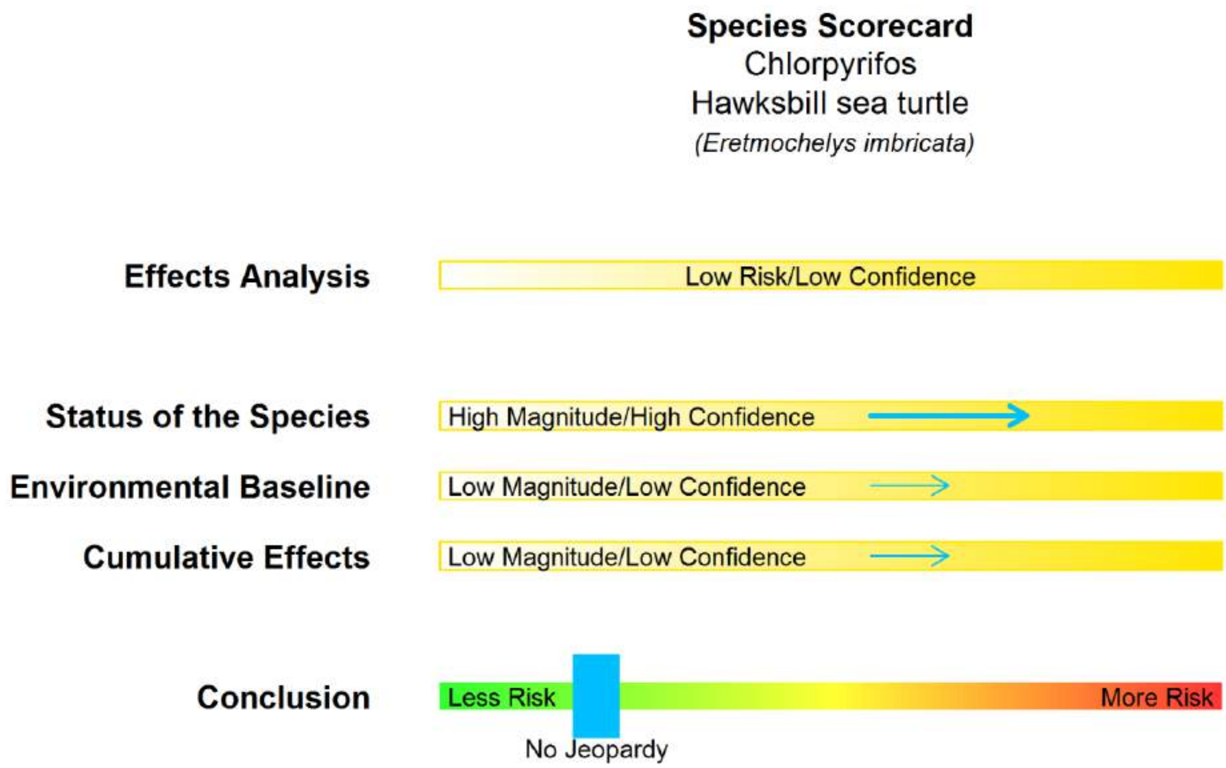

Figure 68. Species Score Card; Hawksbill sea turtle; Chlorpyrifos

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Population abundance improving in Atlantic and Indian Ocean; abundance declining in Pacific Ocean over the last 20 - 100 years. 68% of nesting sites exhibited declines.
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

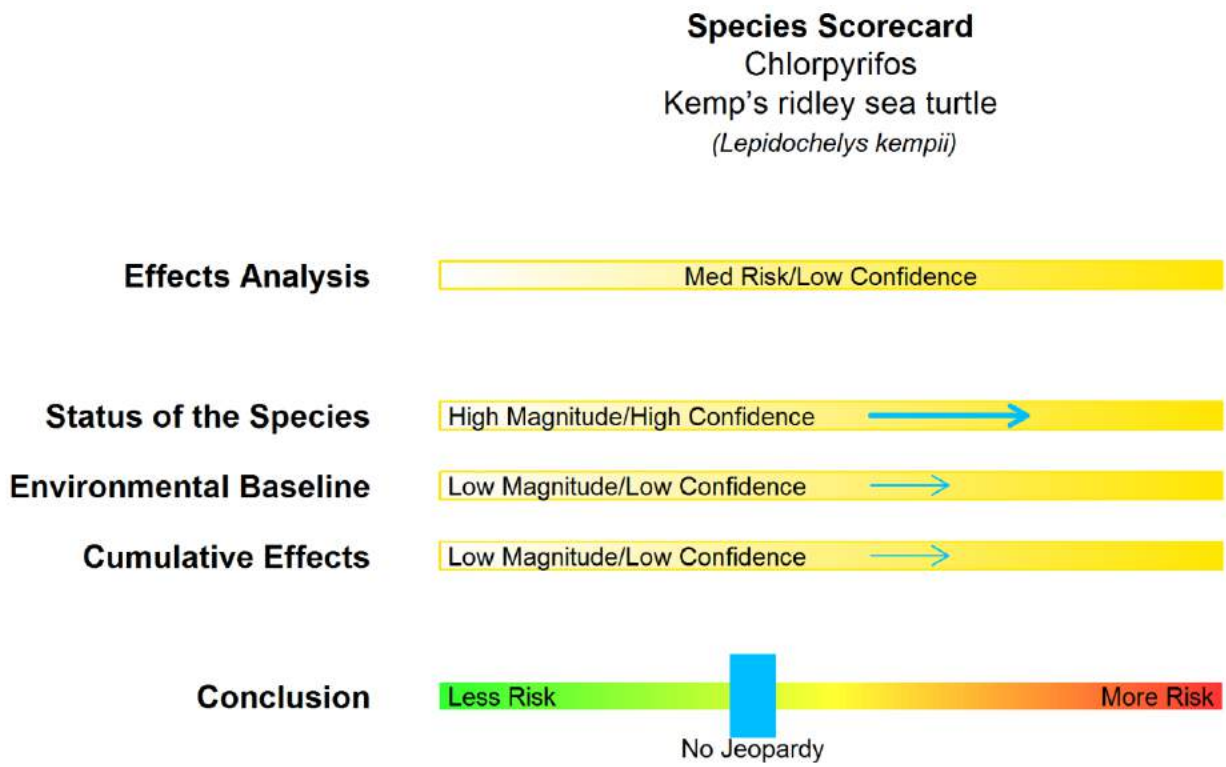

Figure 69. Species Score Card; Kemp's ridley sea turtle; Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence</u>

- Abundance trends negative;
- Endangered;
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

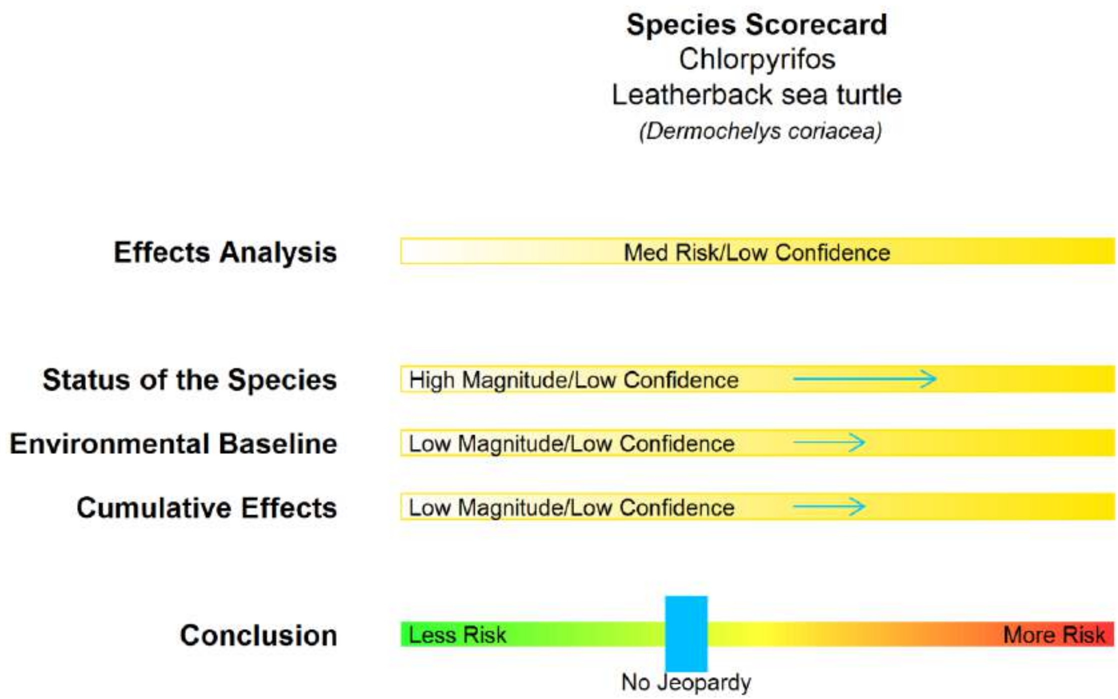

Figure 70. Species Score Card; Leatherback sea turtle; Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Minimal increased risk of jeopardy; High magnitude/ Low confidence</u>

- Pacific population declined from 81,000 in to less than 3,000 with a continued rate of loss of approximately 6 %. Atlantic population is stable and showing signs of increasing growth of between 4-5.6% and 9-13% in Florida and the U.S. Virgin Islands, respectively.
- Endangered;
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

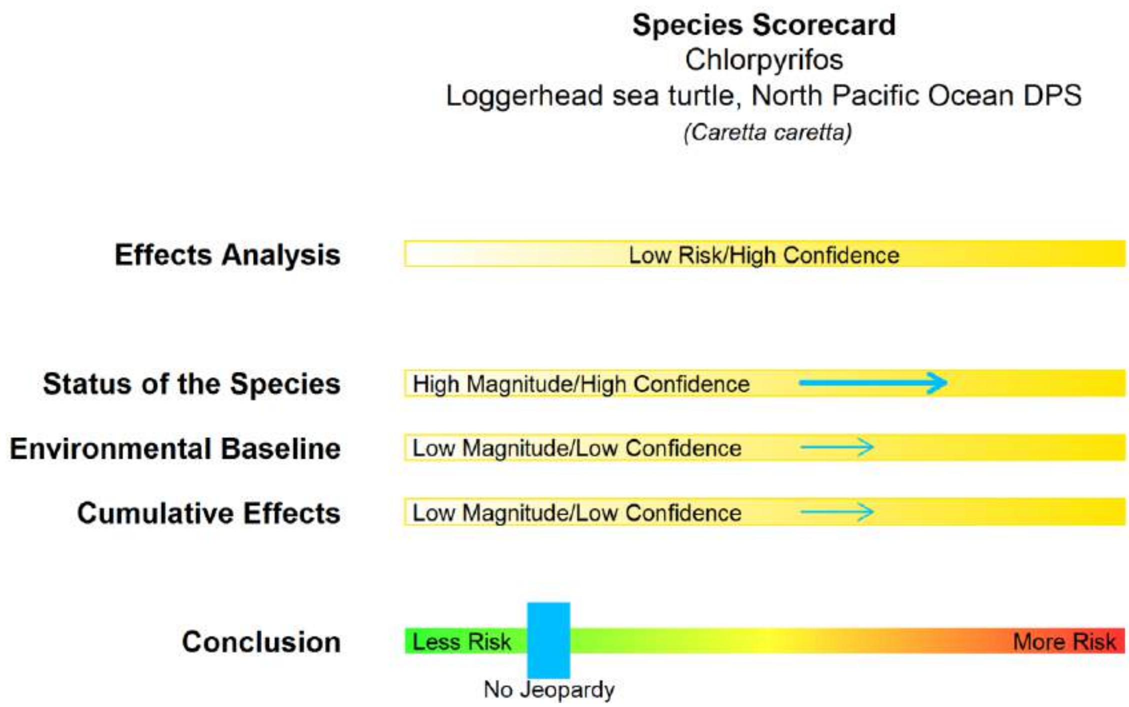

Figure 71. Species Score Card; Loggerhead sea turtle, North Pacific Ocean DPS; Chlorpyrifos

Effects Analysis: Low risk/High confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Population growth rate estimated at 0.032. Population depressed compared to historical numbers.
- Threatened; Population has declined an estimated 80% in past 20 years.
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

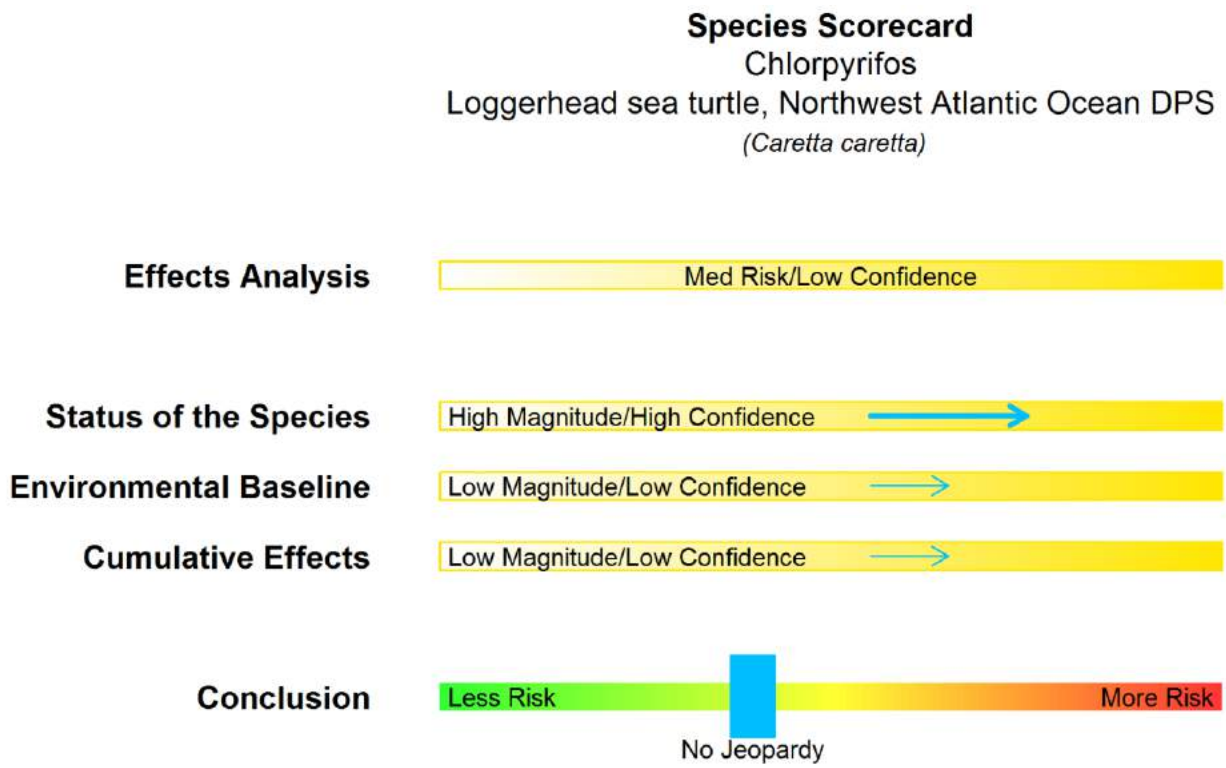

Figure 72. Species Score Card; Loggerhead sea turtle, Northwest Atlantic Ocean DPS; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- All sub-populations exhibiting negative population growth rates;
- Threatened;
- Recovery criteria not met;

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

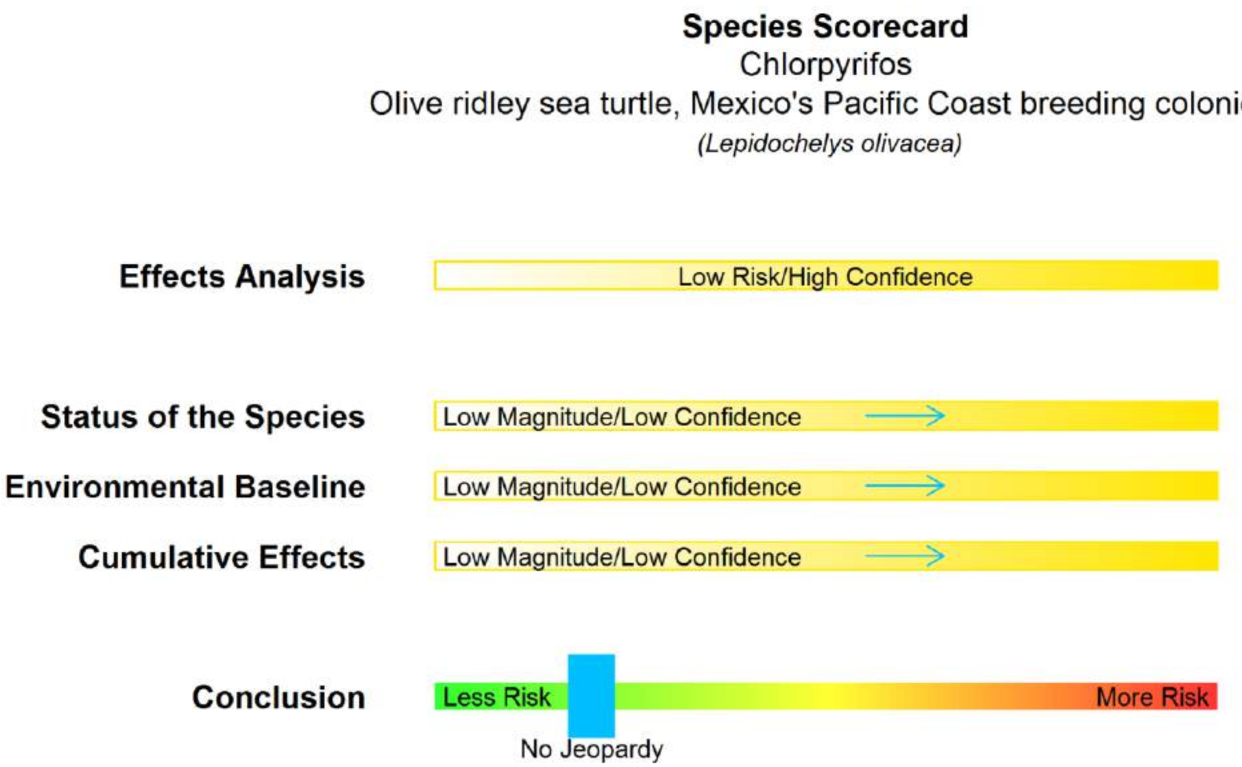

Figure 73. Species Score Card; Olive ridley sea turtle, Mexico's Pacific Coast breeding colonies; Chlorpyrifos

Effects Analysis: Low risk/High confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- 50% decline in a population abundance since the 1960's; 80% reductions in some nesting populations in the Western Atlantic Ocean since 1967;
- Threatened;
- Recovery criteria not met;

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

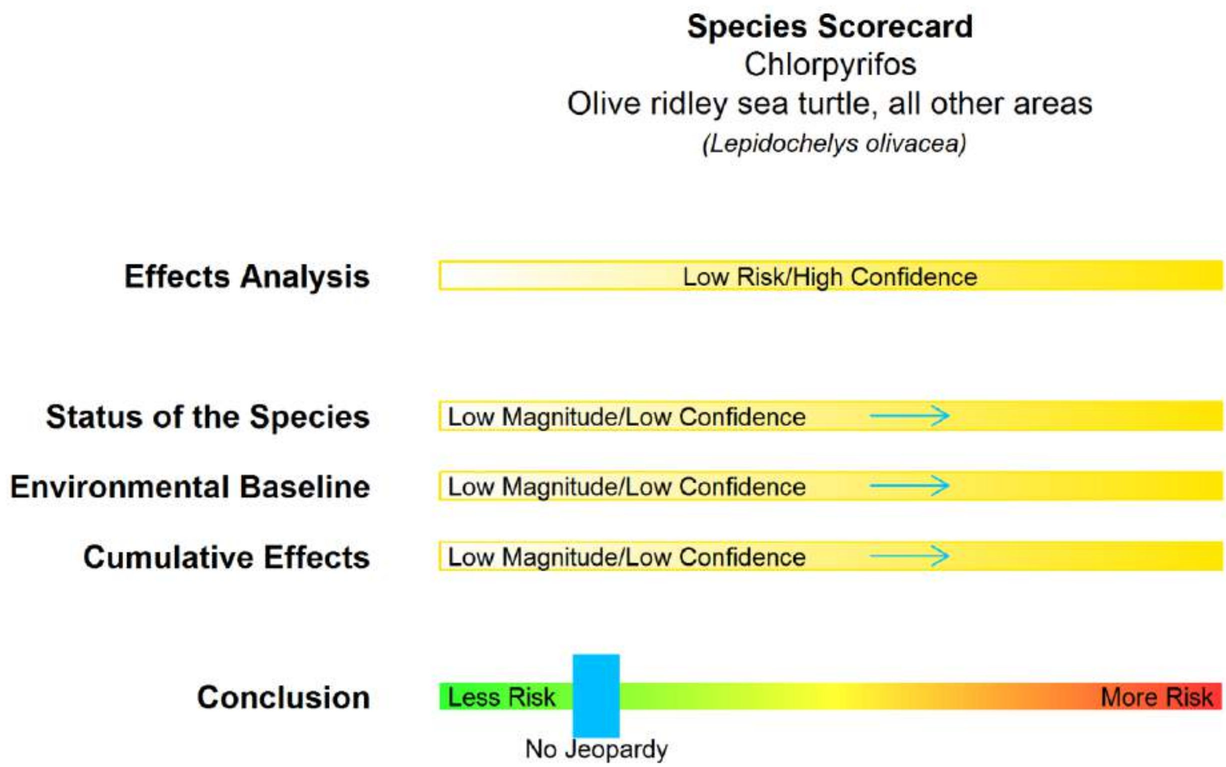

Figure 74. Species Score Card; Olive ridley sea turtle, all other areas; Chlorpyrifos

<u>Effects Analysis: Low risk/High confidence</u>

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Some nesting populations are stable or increasing, but most remain severely depressed. Populations are outside of the action area.
- Threatened;
- Recovery criteria not met;

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters but effects uncertain

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

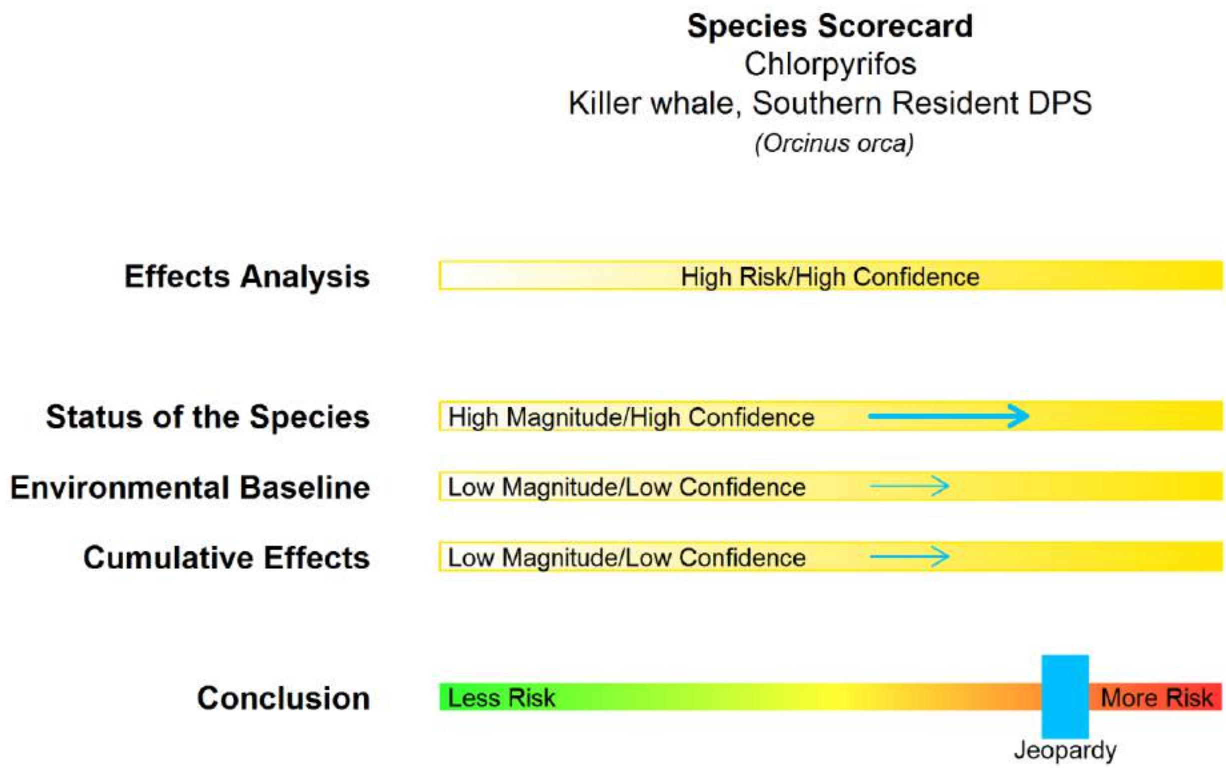

Figure 75. Species Score Card; Killer whale, Southern Resident DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reduced abundance anticipated based on effects to prey (Chinook salmon)
- Anticipated effects include reduced availability of Chinook salmon and other fish prey leading to reduced growth, chronic lack of food;

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Stable to declining populations in past decade, unstable population structure
- Endangered, very small population size (n=76 individuals);
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/Low confidence

- Elevated temperatures may occur in marine habitats;
- Environmental mixtures anticipated in marine habitats with high uncertainty of toxicity

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures may occur in marine waters

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to orca whales' prey base. We have high confidence in exposure concentrations predicted for freshwater habitats. The species prey is most at risk while spawning, rearing, and migrating in freshwaters. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action due to continuous reductions in prey.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

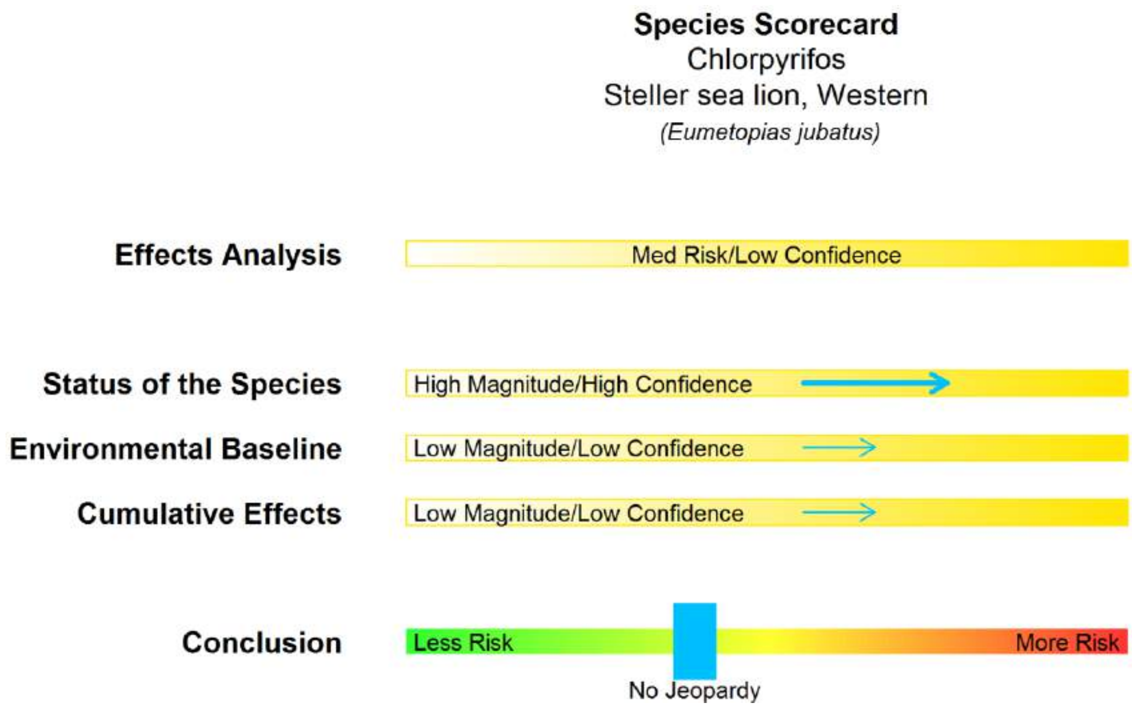

Figure 76. Species Score Card; Steller sea lion, Western; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include reduced prey abundance

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- 30% of 1950s historical abundance, stable to slight negative population trend;
- Endangered;
- Recovery criteria not met;

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect sea lions
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk from reductions in prey. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

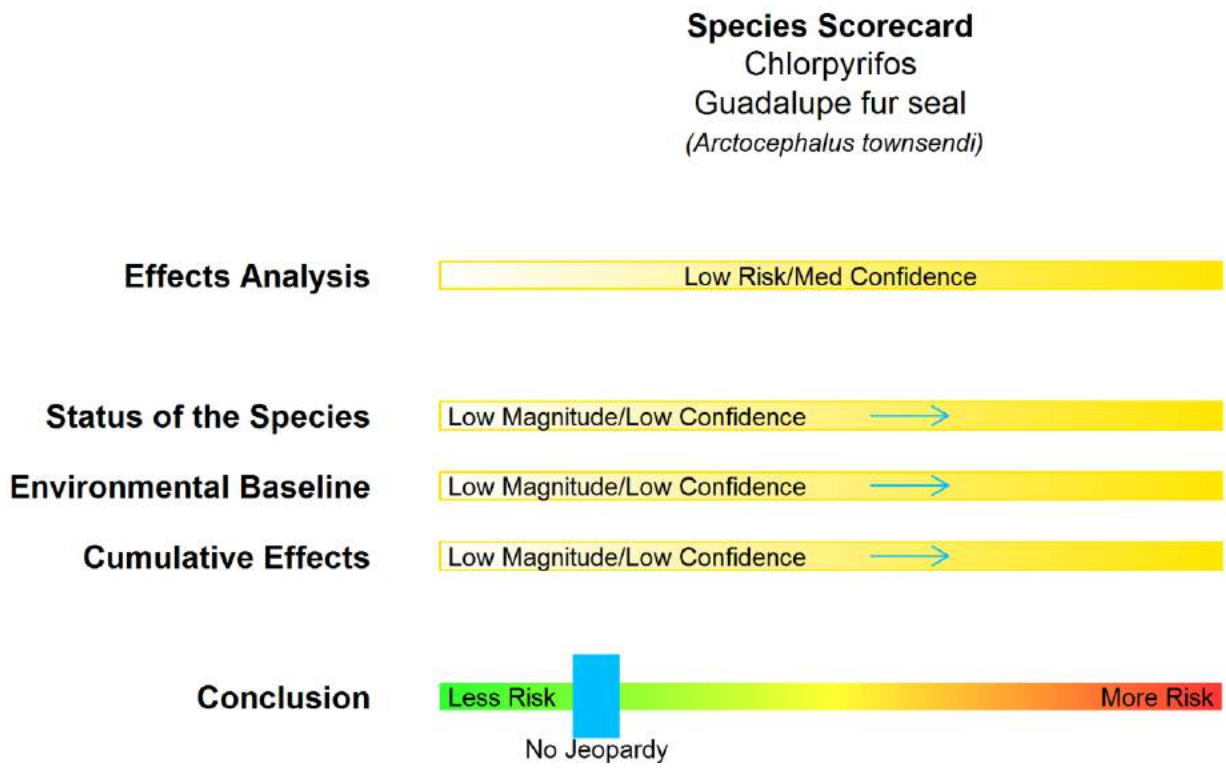

Figure 77. Species Score Card; Guadalupe fur seal; Chlorpyrifos

<u>Effects Analysis: Low risk/Medium confidence</u>

- Reduced abundance not anticipated
- Potential effects include reduced prey abundance

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- 5% of historical abundance, increasing abundance trend;
- Threatened;
- No recovery criteria established;

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters not anticipated to affect sea lions
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters but effects uncertain

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk from reductions in prey. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

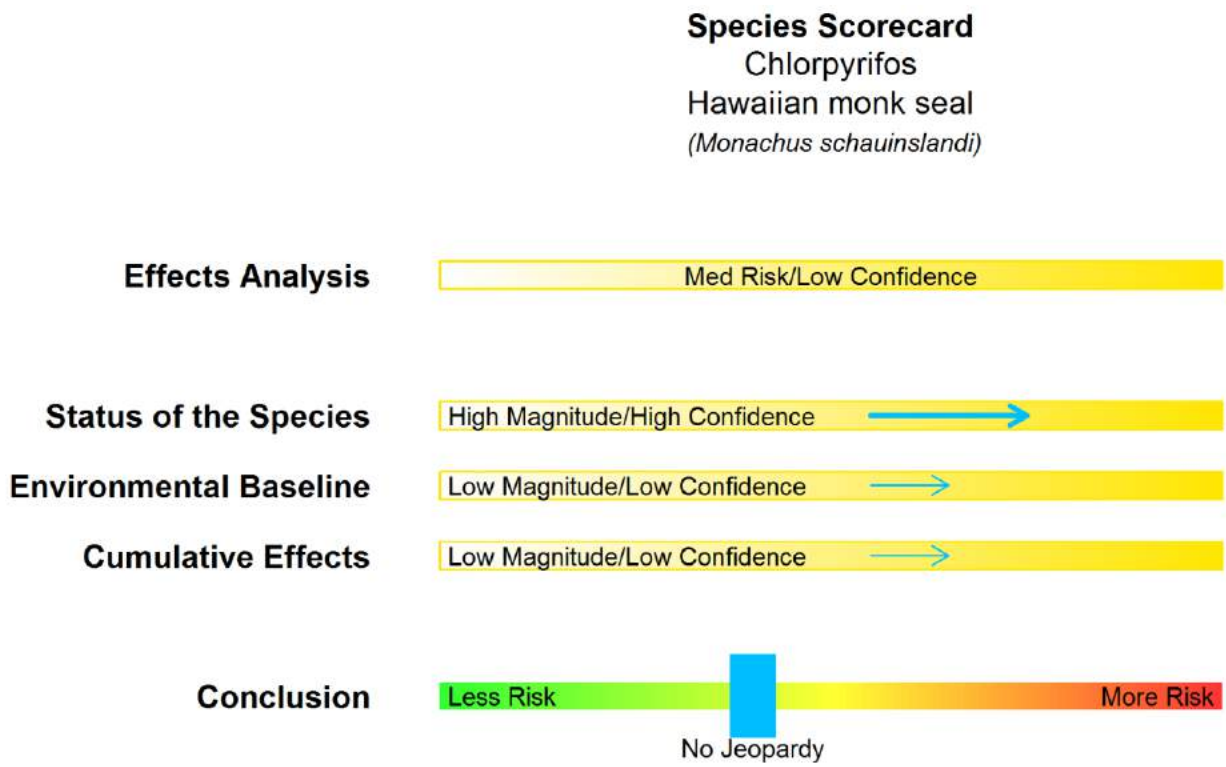

Figure 78. Species Score Card; Hawaiian monk seal; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include reduced prey abundance

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- <40% of 1958 abundance, two populations have increasing trends, six populations have declining trends, very low genetic diversity
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters not anticipated to affect sea lions
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk from reductions in prey. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy

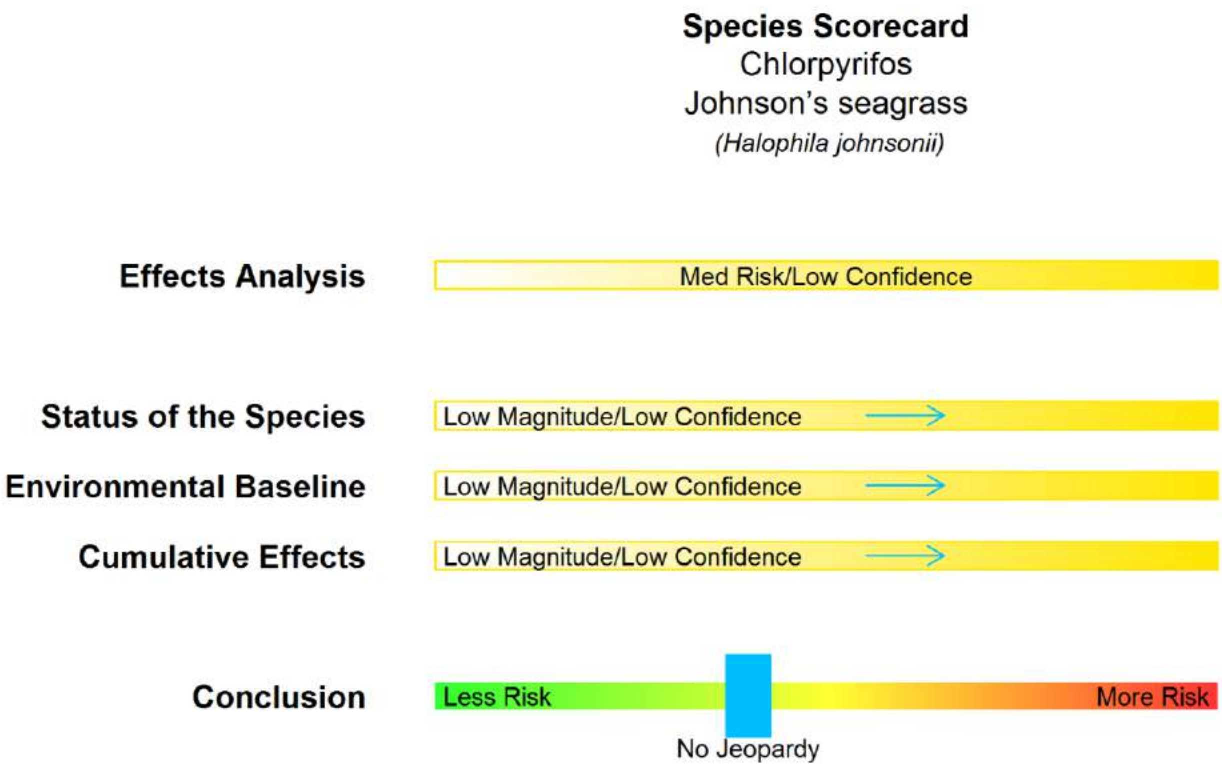

Figure 79. Species Score Card; Johnson's seagrass; Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance not anticipated
- Potential effects include phytotoxicity, primarily from use on developed areas

<u>Status of the Species: Increased risk of jeopardy; Low magnitude/ Low confidence</u>

- No trend data on abundance
- Threatened;
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters not anticipated to affect seagrass
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters but effects uncertain

<u>Conclusion:</u> In marine habitats, we find a high likelihood of exposure and a low likelihood of effects to the species based on low confidence in exposure concentrations and low toxicity. The species is most at risk from direct toxicity. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Chlorpyrifos is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

CHAPTER 20

INTEGRATION AND SYNTHESIS FOR LISTED SPECIES

DIAZINON

TABLE OF CONTENTS

20 DIAZINON

20.1 Introduction

The integration and synthesis section is the final step in our assessment of the risk posed to species and critical habitat as a result of implementing the proposed action. In this section, we add the effects of the action (Chapter 13) to the environmental baseline (Chapter 10) and the cumulative effects (Chapter 18) to formulate the agency's biological opinion as to whether the proposed action is likely to: (1) reduce appreciably the likelihood of both the survival and recovery of an Endangered Species Act (ESA)-listed species in the wild by reducing its numbers, reproduction, or distribution; or (2) appreciably diminish the value of designated critical habitat for the conservation of an ESA-listed species. These assessments are made in full consideration of the Status of the Species (Chapter 9).

We treat the information from the status of the species, environmental baseline, and cumulative effects, as "risk modifiers," in that the effects described in the Effects Analysis section may be modified by the condition of the species; the condition of environmental baseline, and the anticipated cumulative effects. The key questions addressed include:

1) Status of the Species:
    - Are abundance, spatial distribution, and productivity trends increasing, decreasing or stable?
    - Is the species listed as threatened, or as endangered?
    - Have recovery goals been met, or are they on a sustained positive trajectory toward recovery?
2) Environmental Baseline:
    - Are freshwater temperatures elevated?
    - Are pesticide mixtures present, or anticipated based on current land use?
3) Cumulative Effects:
    - Will future temperatures impair species aquatic habitats?
    - Will future hydrologic flows impair freshwater species habitats?

Once each of the above sections is evaluated i.e., questions answered, the effects of the action and the risk modifiers are depicted graphically on a "scorecard." First, we assign a magnitude of influence (low or high) indicated graphically with one of two lengths of arrows. The shorter of the two arrows indicates a low magnitude, while the longer of the two arrows indicates a high magnitude as a risk modifier. The direction an arrow is pointed indicates the directionality of the risk modifier. For example, an environmental baseline arrow pointing towards more risk may indicate that environmental mixtures and elevated temperatures occur in the Environmental Baseline, which further stresses the species in question. We also assign a level of confidence in our selection of the small and large magnitude, indicated by a bold arrow (high confidence) or an un-bolded arrow (low confidence). The final arrow representing the influence on risk is graphically depicted on each species' scorecard.

Figure 1. Example of arrows to represent direction, magnitude, and confidence of risk modifiers

Conclusion Section:
With full consideration of the status of the species and the designated critical habitat, we construct a description of the effects of the action within the action area on populations or subpopulations, when added to the environmental baseline and the cumulative effects, to determine whether the action could reasonably be expected to:

- Reduce appreciably the likelihood of survival and recovery of ESA-listed species in the wild by reducing its numbers, reproduction, or distribution, and state our conclusion as to whether the action is likely to jeopardize the continued existence of such species; or
- Appreciably diminish the value of designated critical habitat for the conservation of an ESA-listed species, and state our conclusion as to whether the action is likely to destroy or adversely modify designated critical habitat.

A scorecard is generated for each species and designated critical habitat. The effects of the proposed action is considered, as modified by the magnitude and confidence of the three arrows. Next, a no-jeopardy or jeopardy bar is placed on the risk bar i.e., the colored bar beginning with green (less risk) to red (more risk) (***Figure 2***).

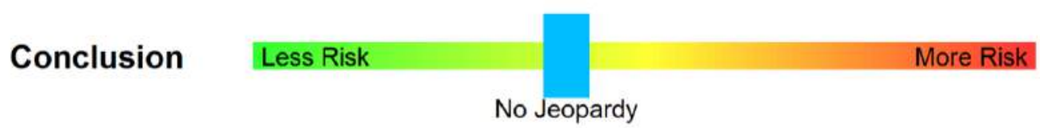

Figure 2: Example conclusion graphic

20.2 Species Scorecards

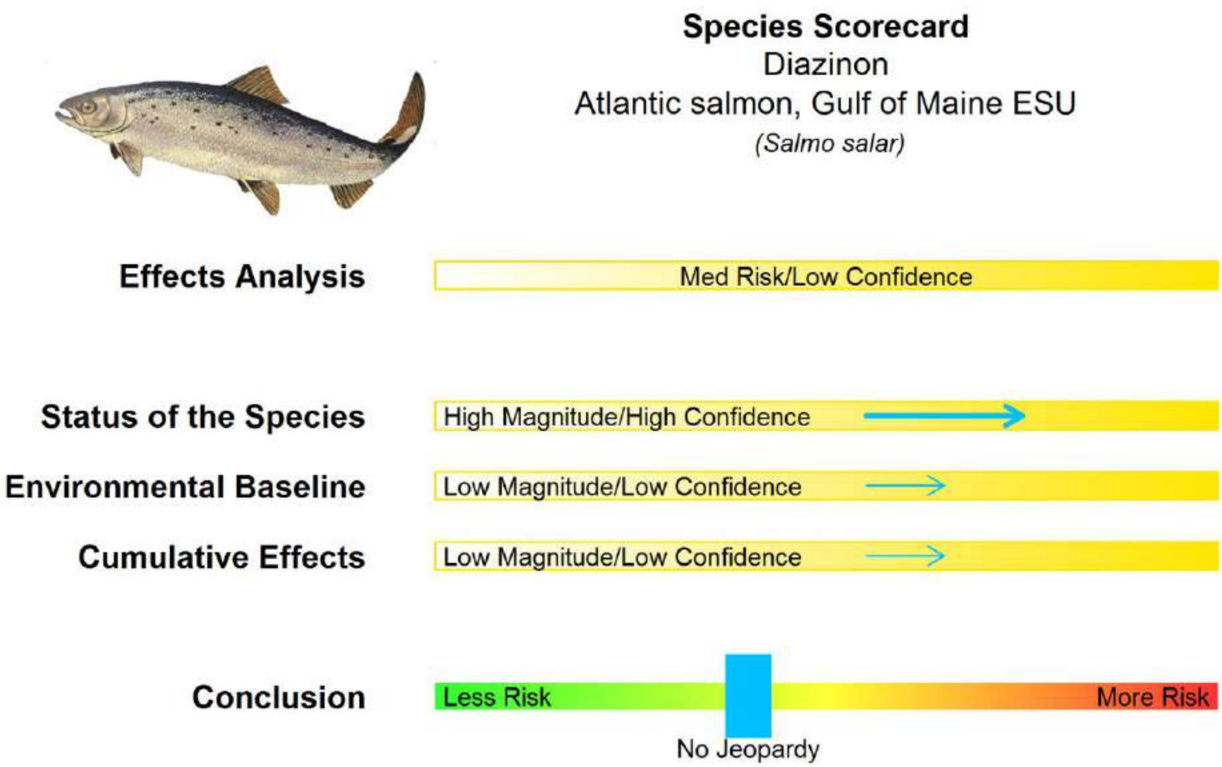

Figure 3. Species Score Card; Atlantic salmon, Gulf of Maine Evolutionarily Significant Unit (ESU); Diazinon

<u>Effects Analysis: Medium risk/Low confidence</u>

- Significant reductions in abundance or productivity not anticipated
- Uncertainty in predicted diazinon concentrations in coastal marine habitats

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Abundance is declining, low resilience to disturbance, sustained by hatcheries
- Proposed action may hinder attainment of recovery goals in coastal areas

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters not anticipated to affect species
- Environmental mixtures not anticipated to substantially affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures in marine areas uncertain to affect species
- No anticipated hydrologic effects in marine waters that would affect species

<u>Conclusion:</u> We find low confidence of a medium level of risk to the species as a whole based on the expected toxicity from uncertain exposure concentrations predicted in saltwater habitats. The species is most at risk while in coastal, estuarine areas where they spend a small portion of their lives. Potential reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

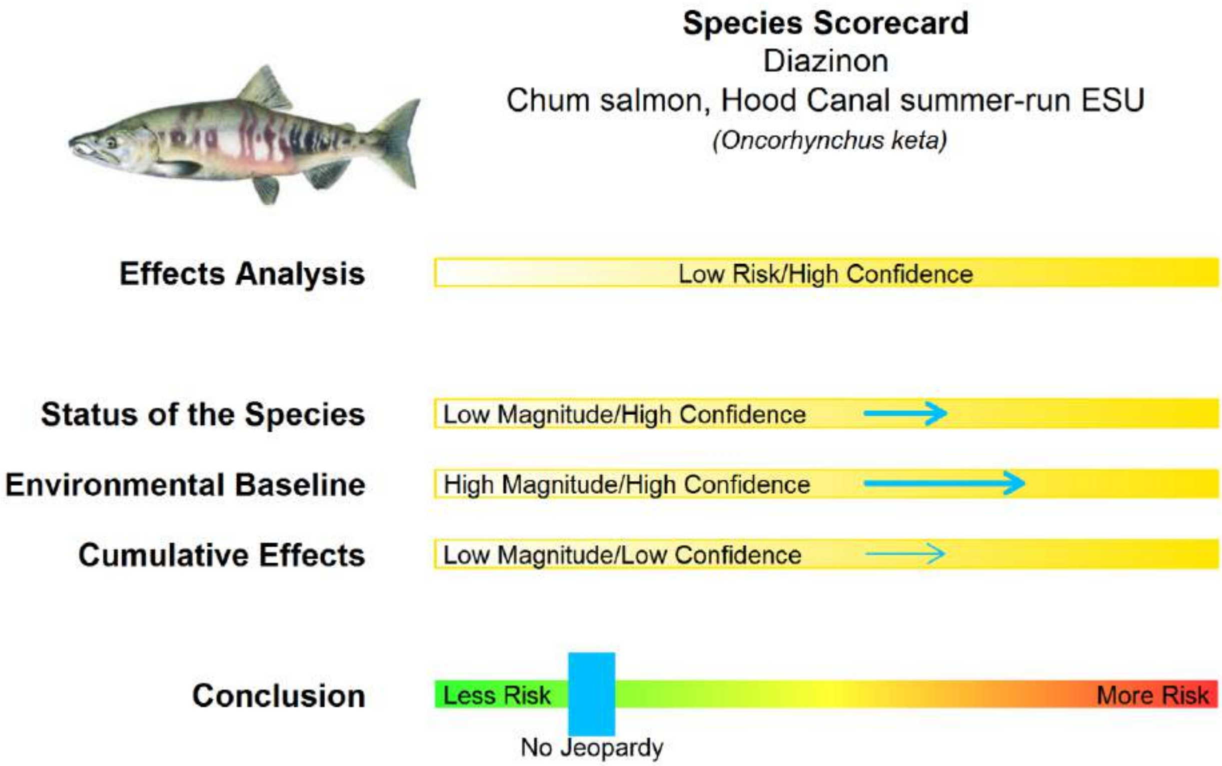

Figure 4. Species Score Card; Chum salmon, Hood Canal summer-run ESU; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence</u>

- Stable to increasing abundance trend, increasing population productivity
- Proposed action may hinder attainment of some recovery goals

<u>Environmental Baseline: Minimal increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures anticipated in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures likely
- Anticipated hydrologic effects in freshwater areas may affect species

<u>Conclusion:</u> We find high confidence of low risk to the species as a whole based on exposure concentrations predicted for freshwater habitats and expected effects to the population. The species is most vulnerable while in freshwater and nearshore areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

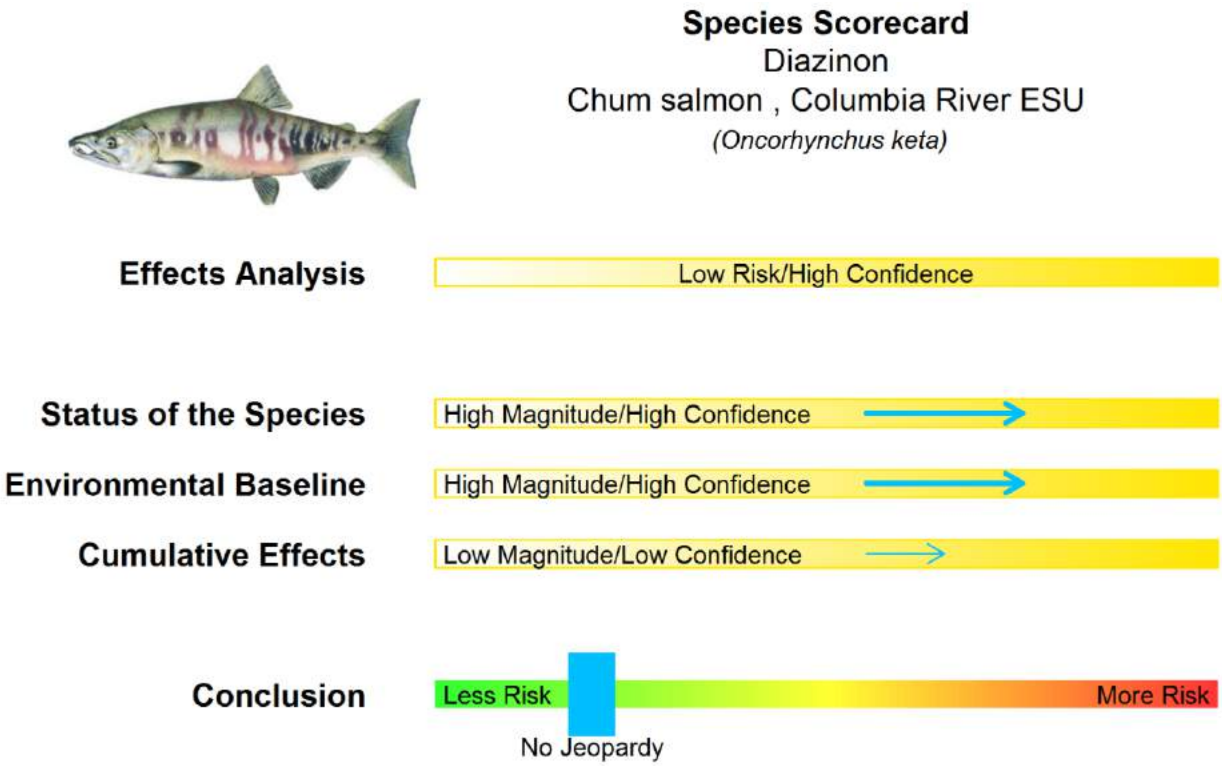

Figure 5. Species Score Card; Chum salmon, Columbia River ESU; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Declining abundance trends, high risk of extinction
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Minimal increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures anticipated in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas that may affect species

<u>Conclusion:</u> We find high confidence in low risk to the species based on exposure concentrations predicted for freshwater habitats and expected population-level effects. The species is most at risk when in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

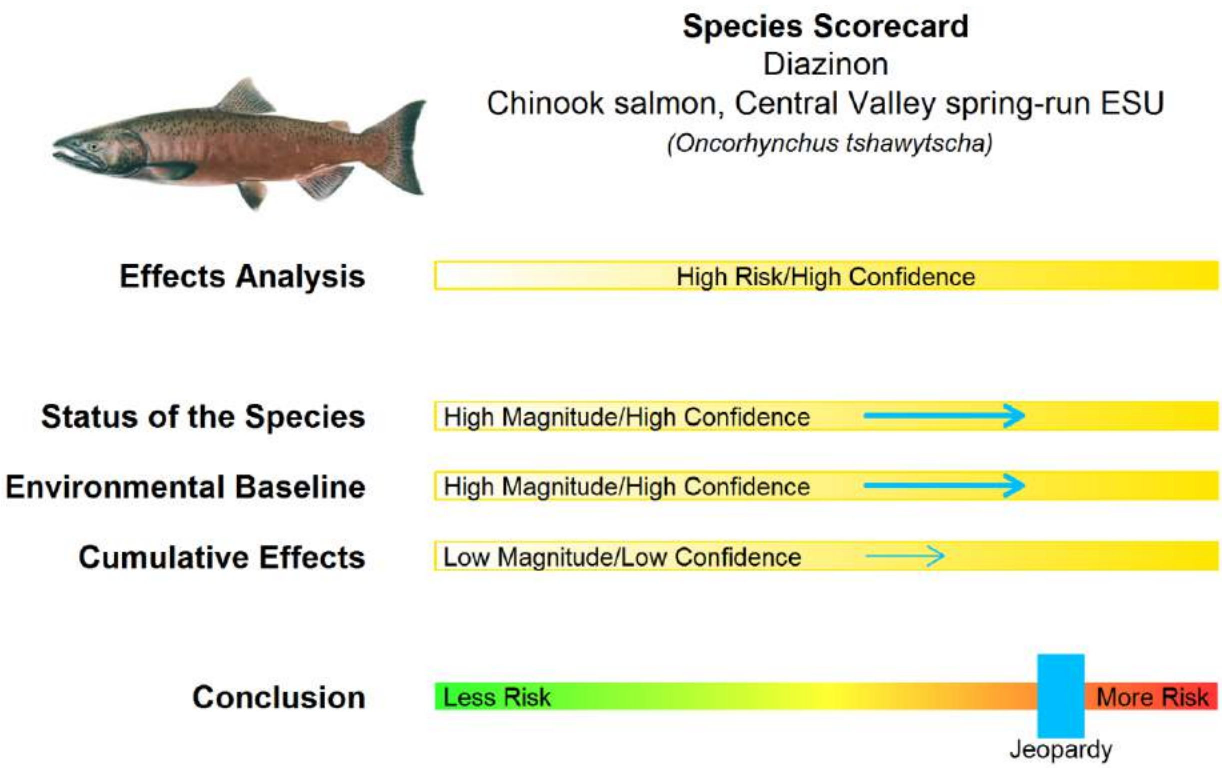

Figure 6. Species Score Card; Chinook salmon, Central Valley spring-run ESU; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Stable to declining abundance trends, low abundances and fragmented populations
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence in high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater habitats where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

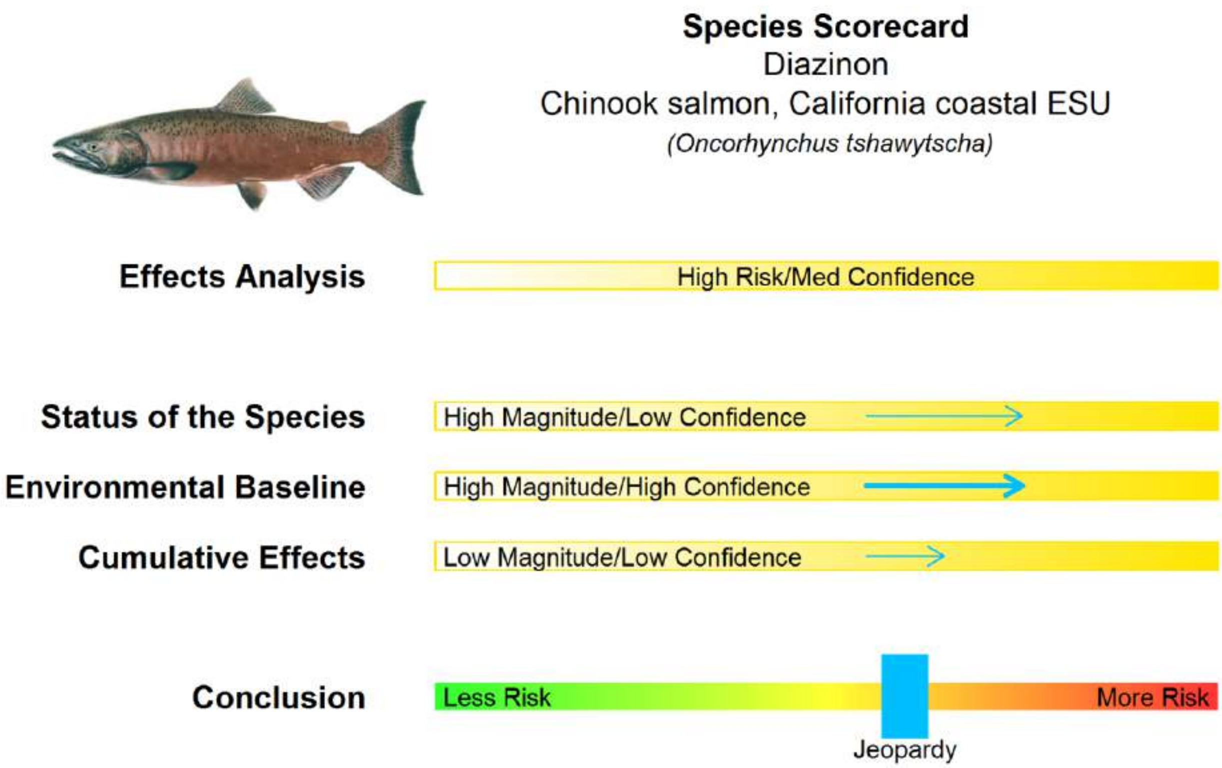

Figure 7. Species Score Card; Chinook salmon, California coastal ESU; Diazinon

<u>Effects Analysis: High risk/Medium confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Minimal increased risk of jeopardy; High magnitude/ Low confidence</u>

- One population with greater than 1000 spawners, declining trends in abundance
- Threatened
- Some recovery criteria not met, yet reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find medium confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

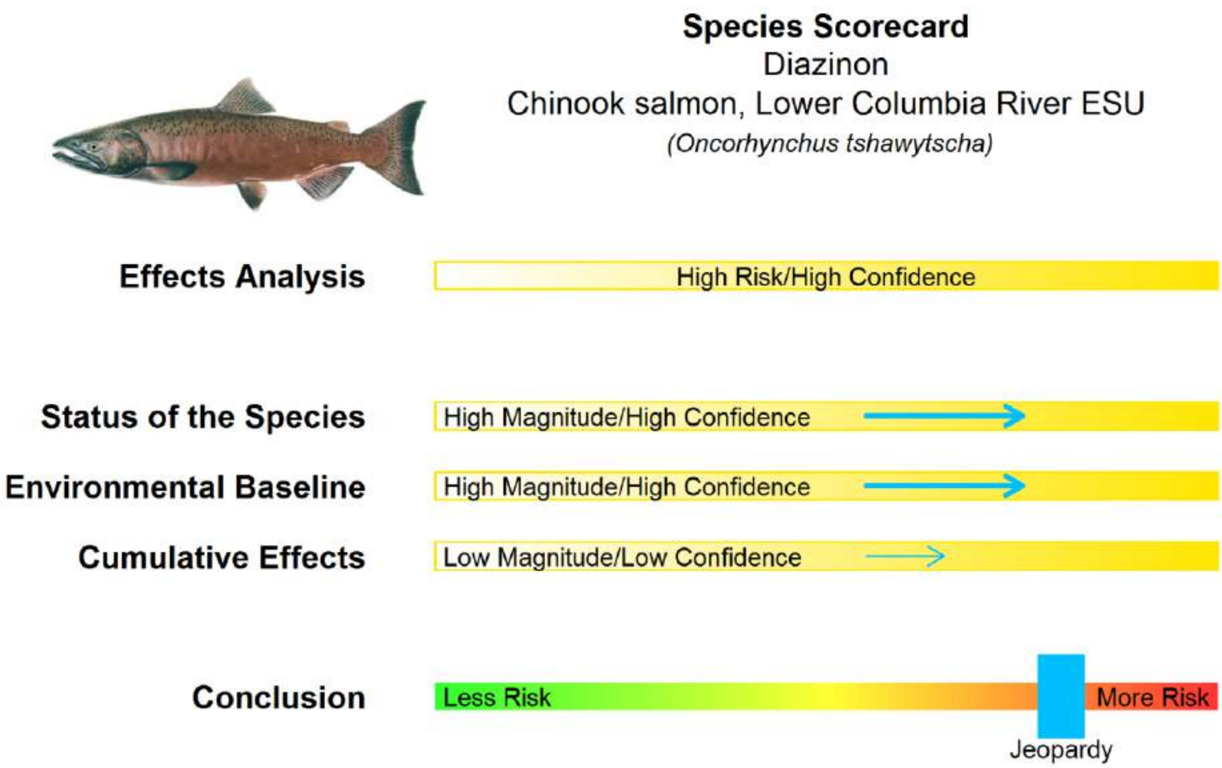

Figure 8. Species Score Card; Chinook salmon, Lower Columbia River ESU; Diazinon

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Declining trends in abundance, one self-sustaining population, low genetic diversity
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Diazinon is likely to jeopardize the continued existence of this species: Jeopardy

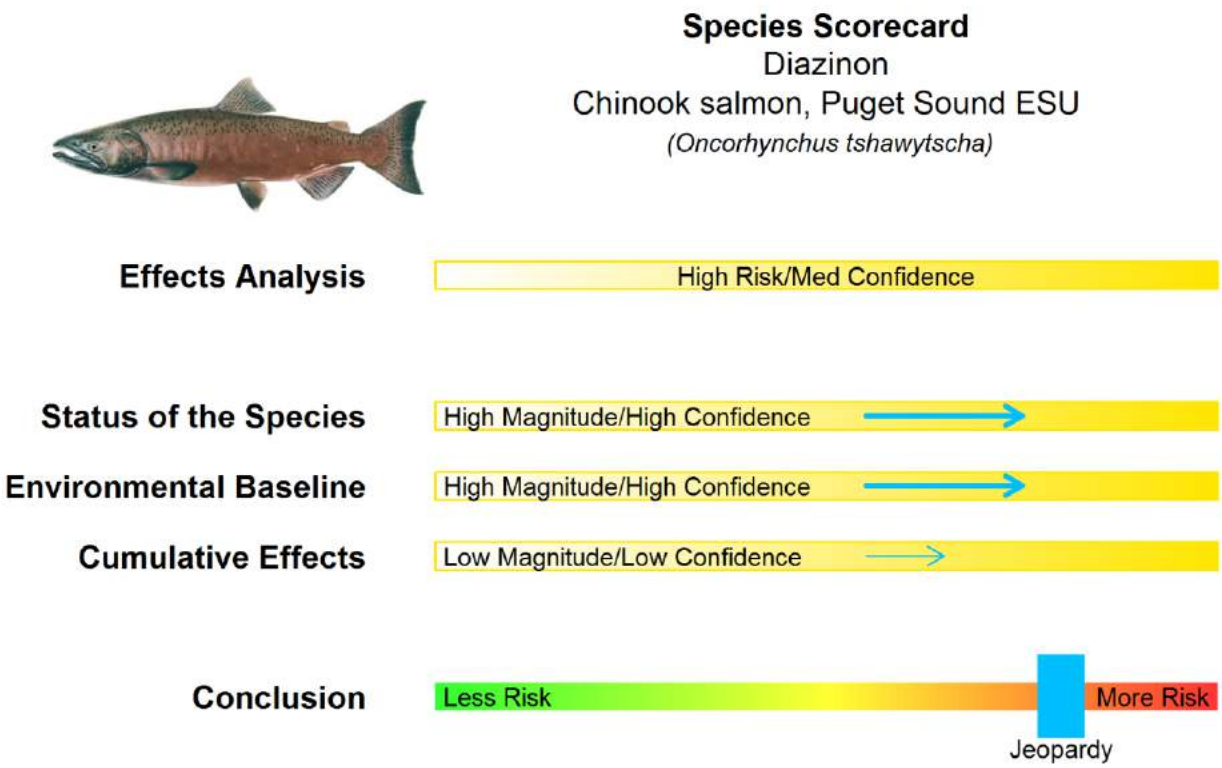

Figure 9. Species Score Card; Chinook salmon, Puget Sound ESU; Diazinon

<u>Effects Analysis: High risk/Medium confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Half of the populations declining and half increasing in abundance
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find medium confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

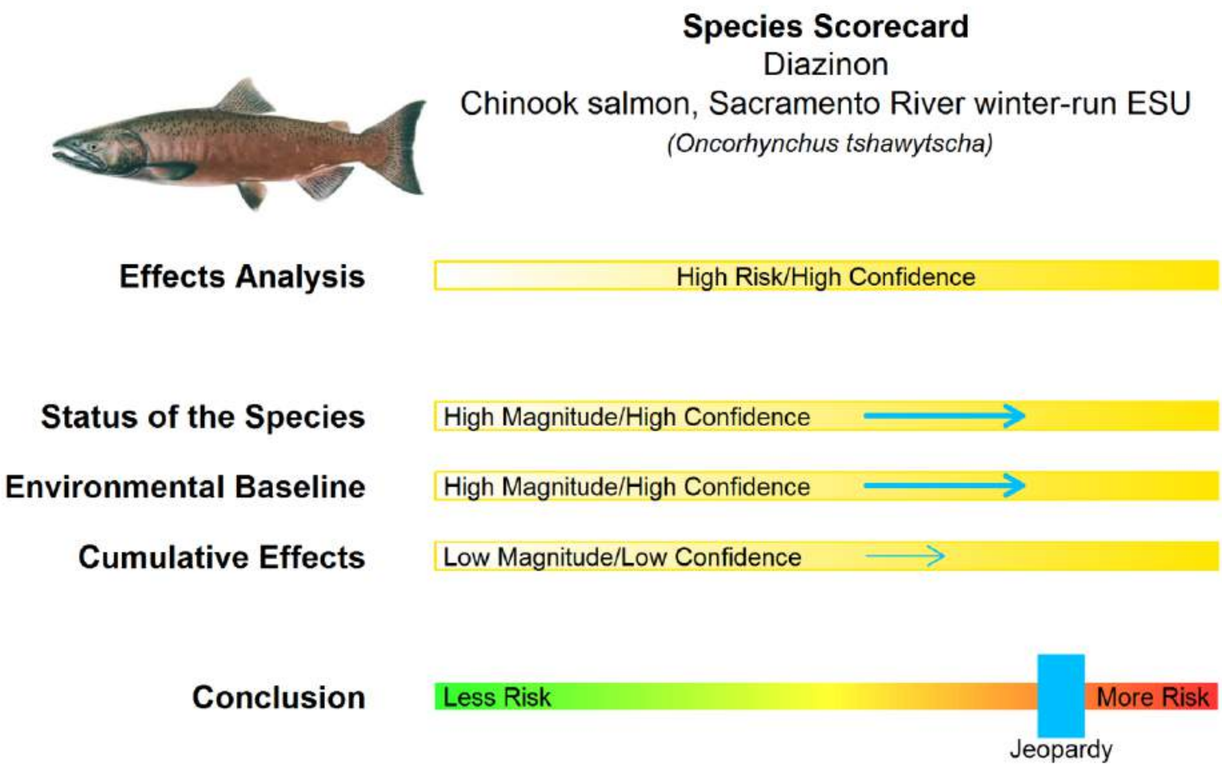

Figure 10. Species Score Card; Chinook salmon, Sacramento River winter-run ESU; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- One extant population, declining abundance trends, hatchery-supported
- Endangered species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Dianinon is likely to jeopardize the continued existence of this species: Jeopardy**</u>

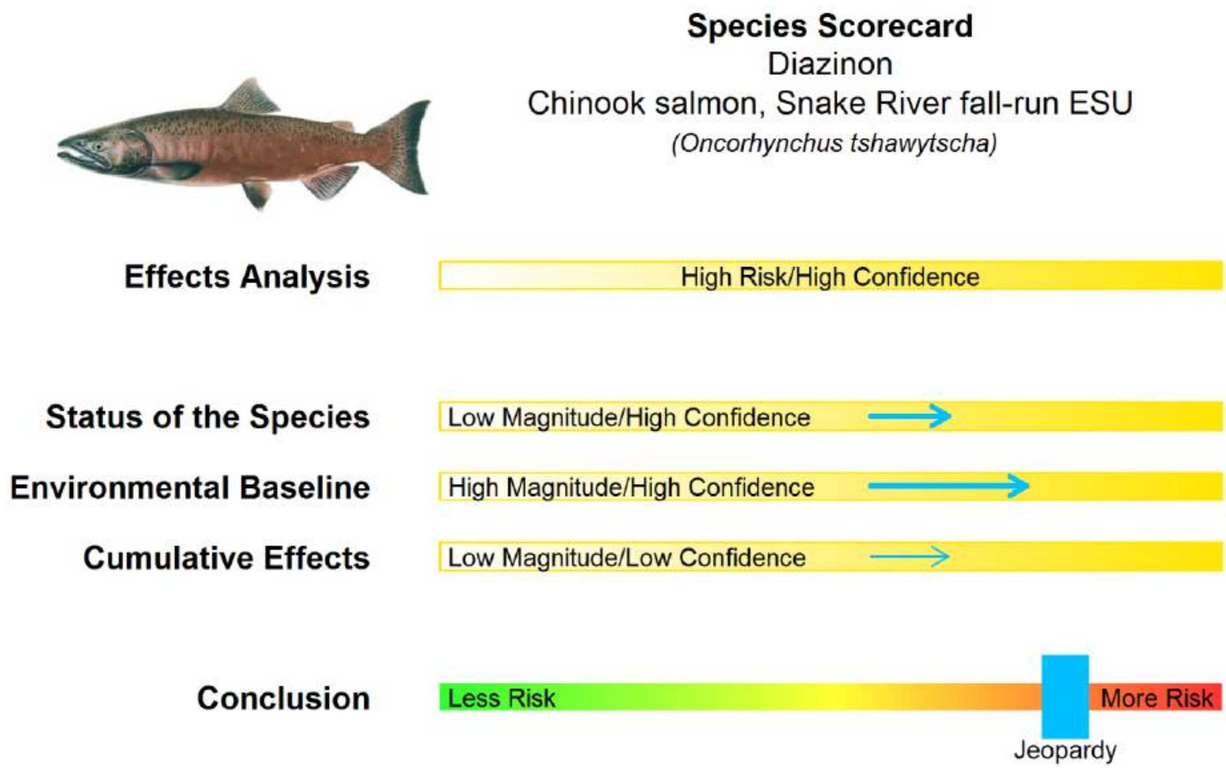

Figure 11. Species Score Card; Chinook salmon, Snake River fall-run ESU; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence</u>

- Stable to increasing abundance trends, moderate extinction risk, hatchery supported
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

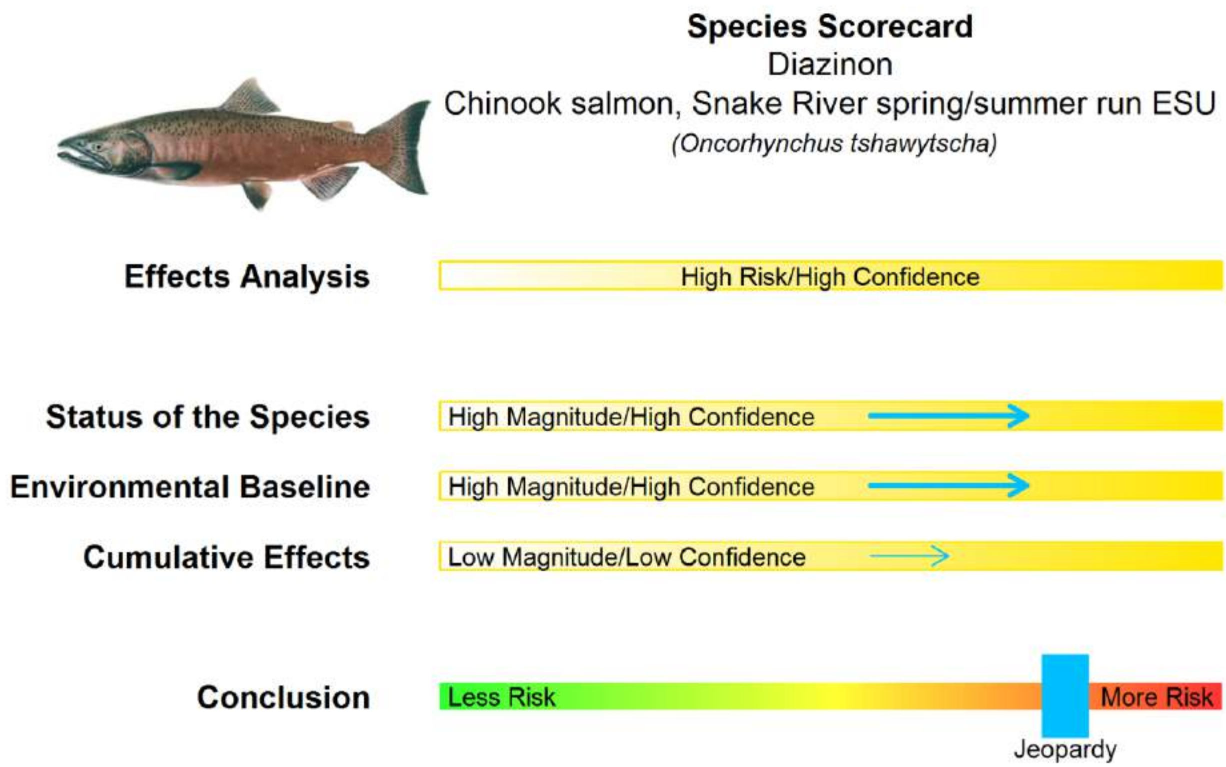

Figure 12. Species Score Card; Chinook salmon, Snake River spring/summer run ESU; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence</u>

- Decreasing abundance trends, high extinction risk, moderate genetic diversity
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

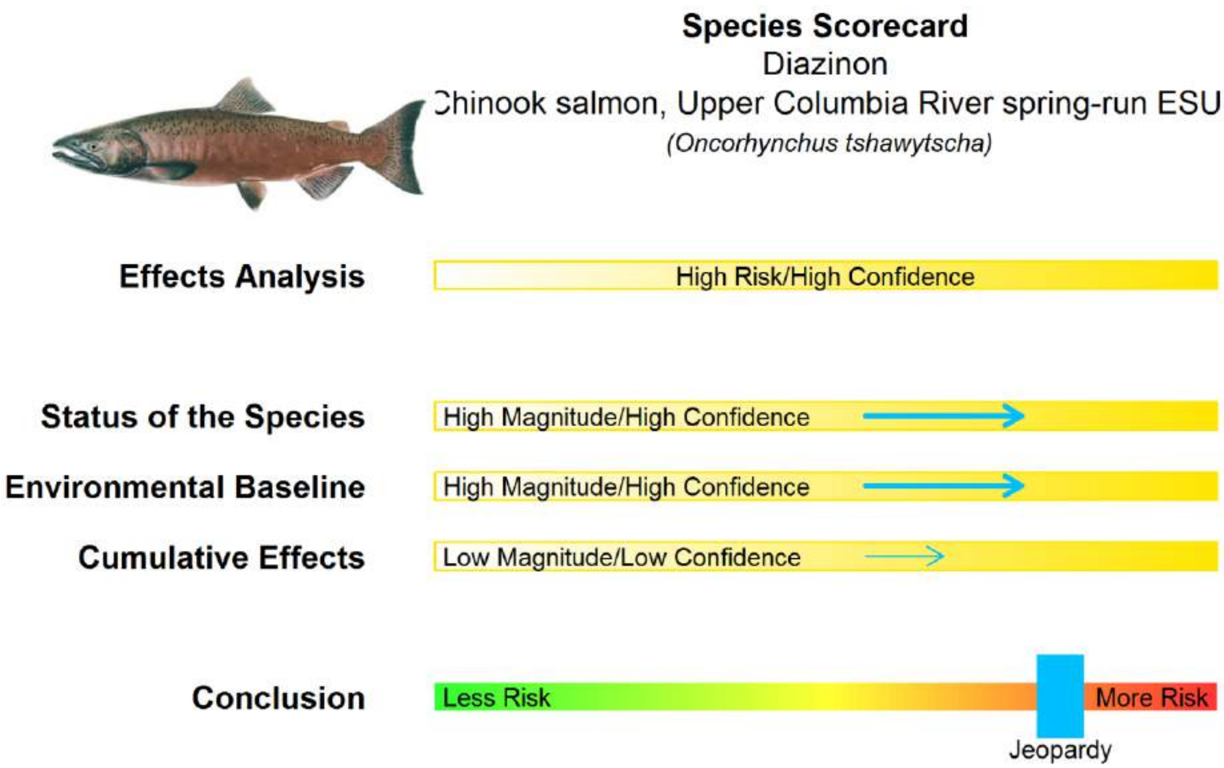

Figure 13. Species Score Card; Chinook salmon, Upper Columbia River spring-run ESU; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Decreasing abundance trends, independent populations not replacing themselves
- Endangered species (all independent population experiencing low abundance)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

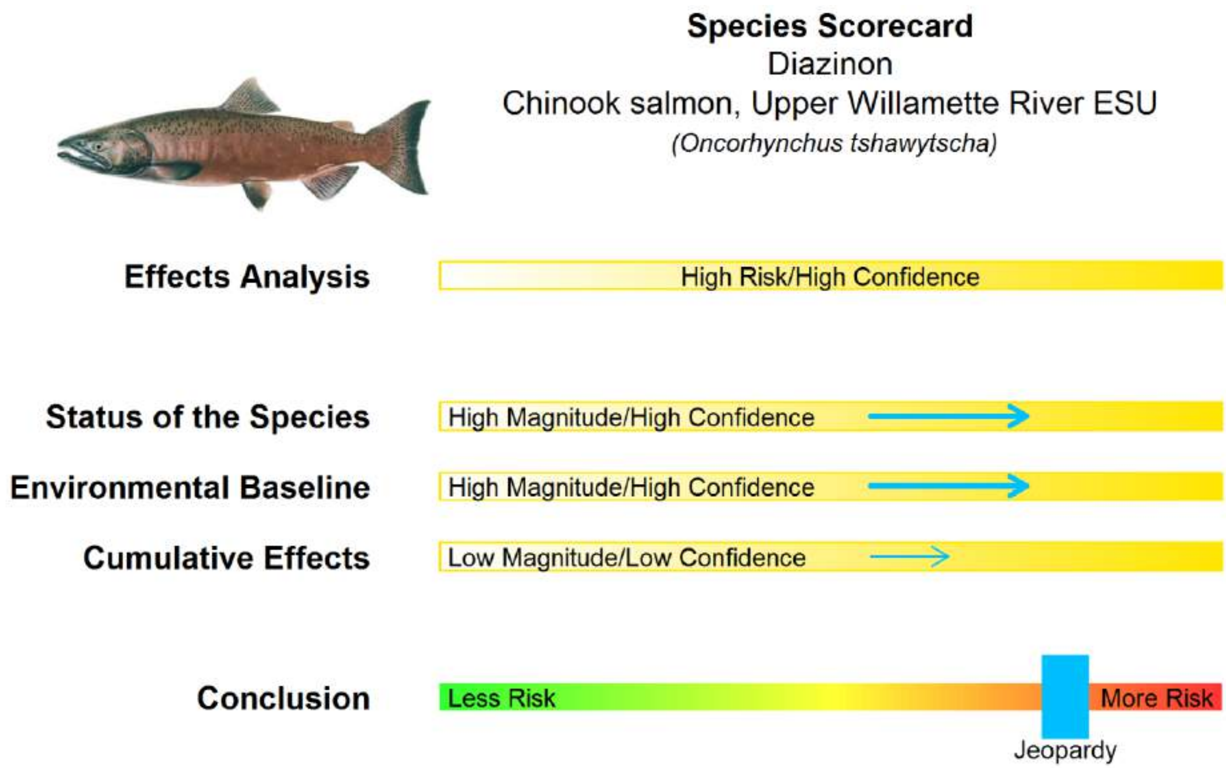

Figure 14. Species Score Card; Chinook salmon, Upper Willamette River ESU; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; How magnitude/ High confidence</u>

- Decreasing abundance trends, 1 of 7 remaining naturally reproducing populations
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

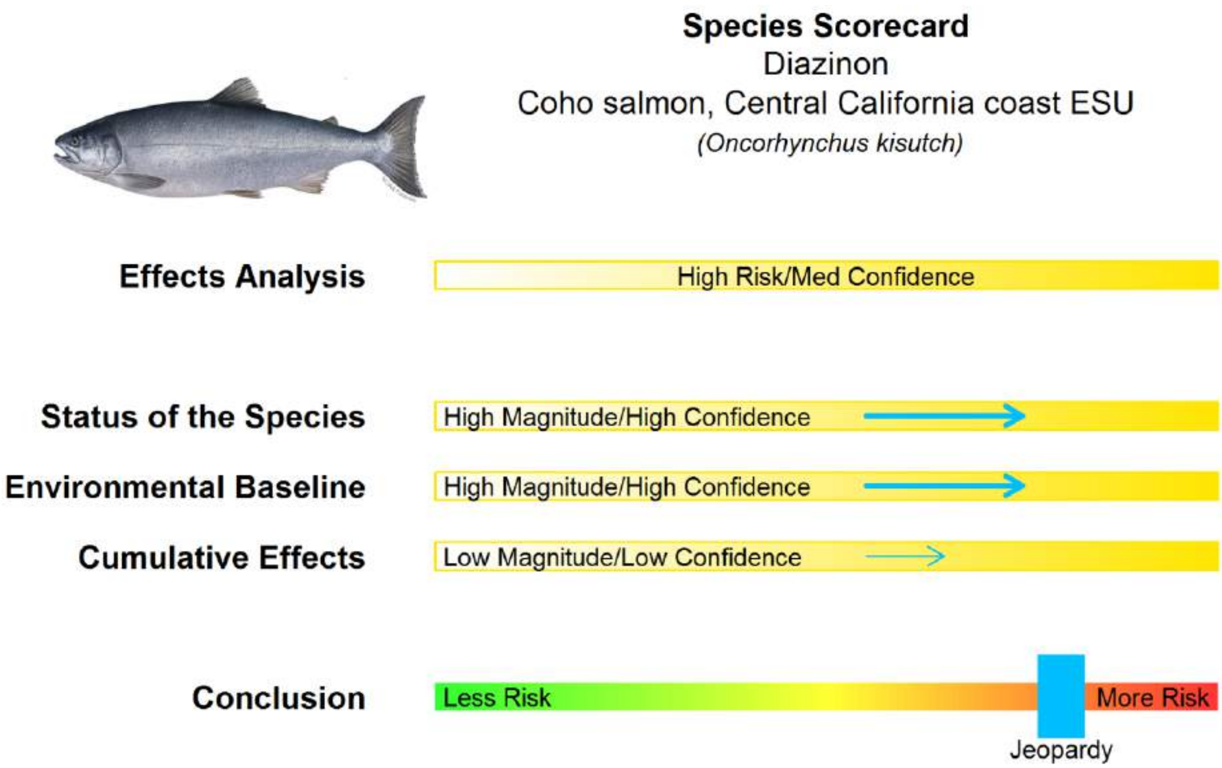

Figure 15. Species Score Card; Coho salmon, Central California coast ESU; Diazinon

<u>Effects Analysis: High risk/Medium confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; How magnitude/ High confidence</u>

- Stable population trend, fragmented populations, supported by hatchery propagation
- Endangered species (low abundances)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find medium confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

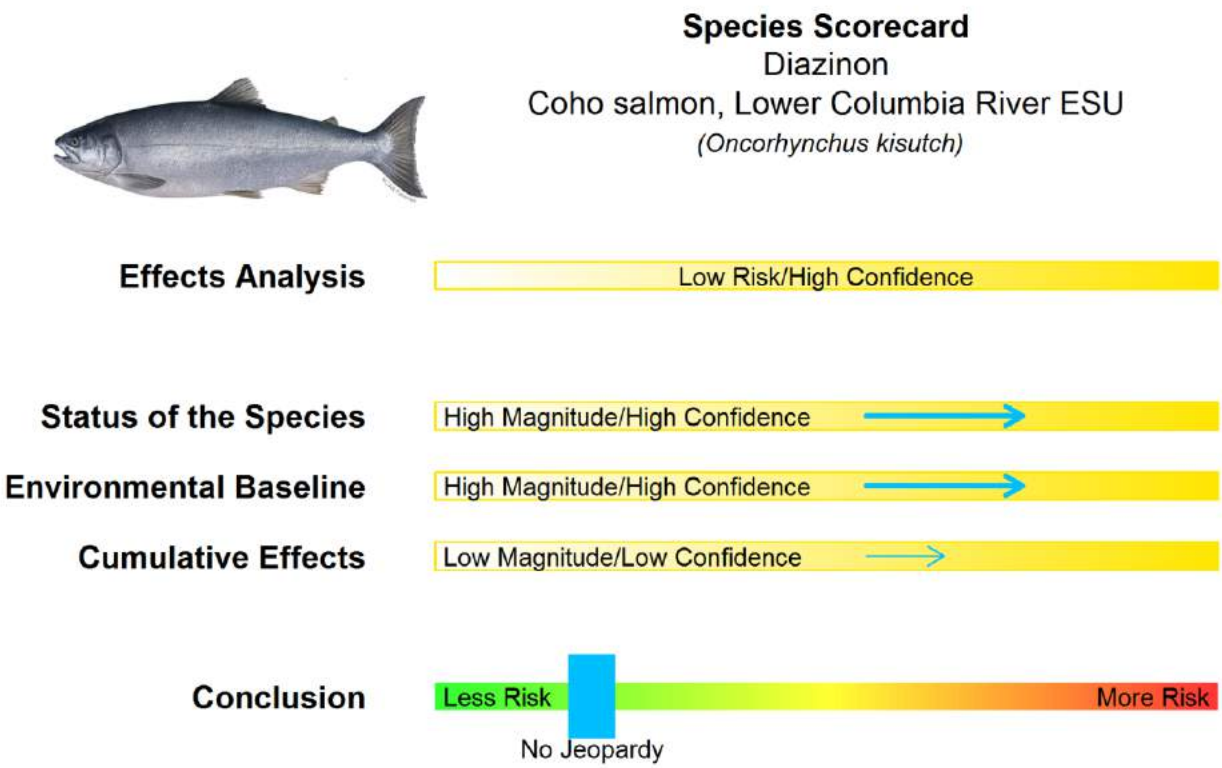

Figure 16. Species Score Card; Coho salmon, Lower Columbia River ESU; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; How magnitude/ High confidence</u>

- Negative long/short term lambda projections. Only 2 of 25 populations exhibit natural production. Diversity in "high risk" category.
- Endangered species (90% reduction in abundance of all independent populations)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species juvenile stage is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>**Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy**</u>

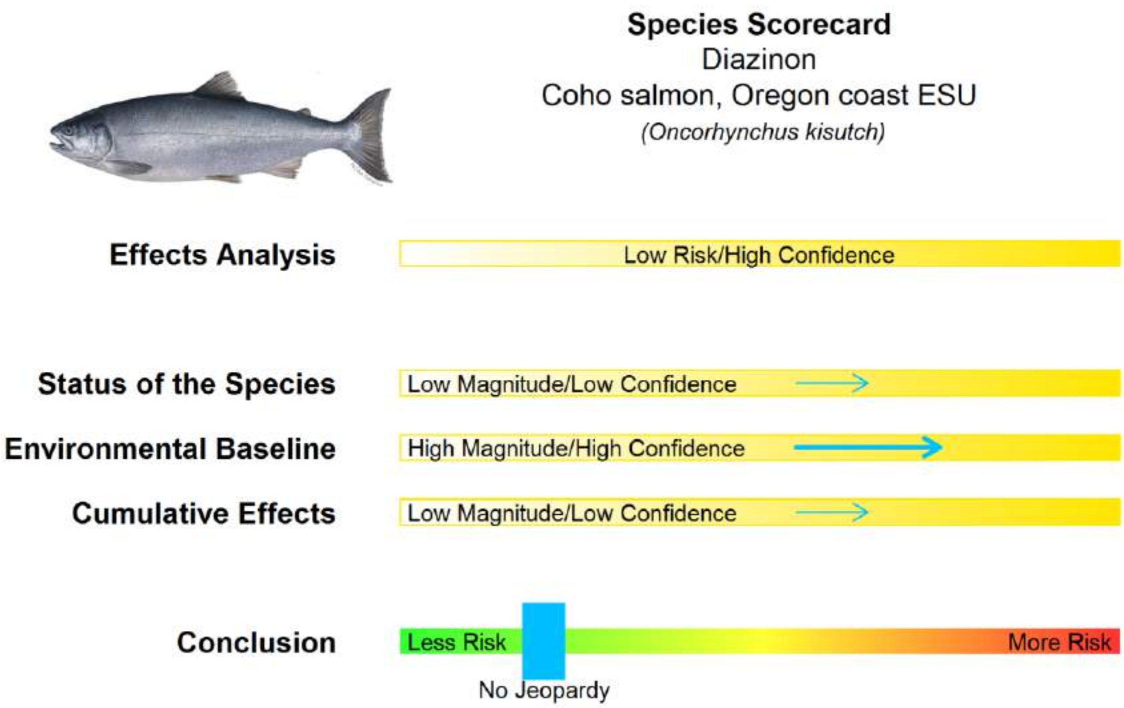

Figure 17. Species Score Card; Coho salmon, Oregon coast ESU; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; How magnitude/ Low confidence</u>

- Variable abundances with periods of severe declines. Negative long term trends negative
- Threatened (Severe reductions in ESU abundance compared to historical estimates)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species juvenile stage is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

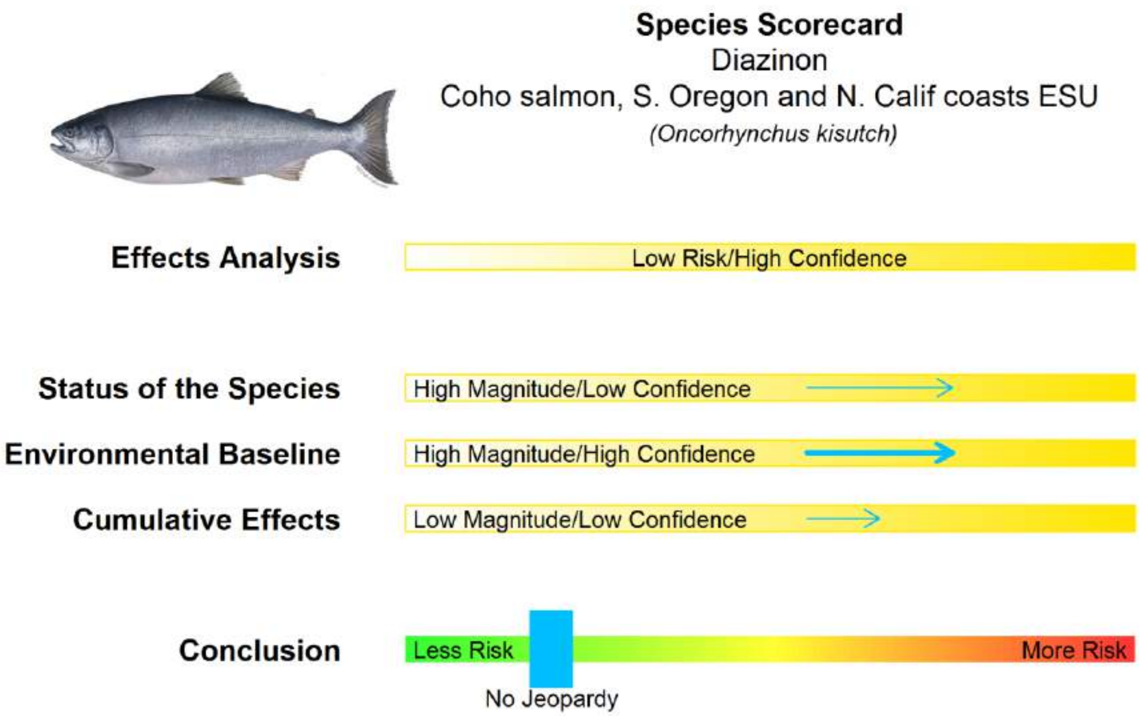

Figure 18. Species Score Card; Coho salmon, S. Oregon and N. Calif coasts ESU; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Limited data on population abundance, thus trend data unavailable
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species juvenile stage is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

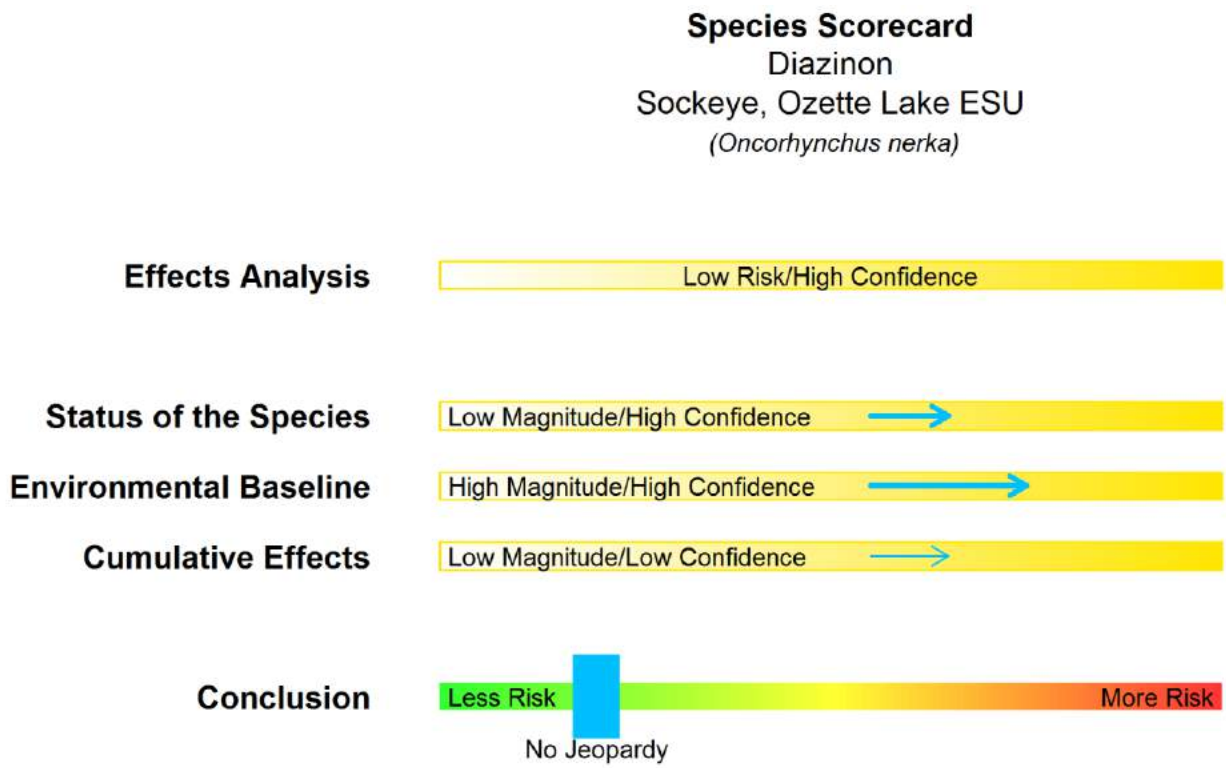

Figure 19. Species Score Card; Sockeye, Ozette Lake ESU; Diazinon

Effects Analysis: Low risk/High confidence

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- Stable productivity rates; low genetic diversity and low resilience to future perturbations
- Threatened (abundance only 1% of historical levels)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species juvenile stage is most at risk while in freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

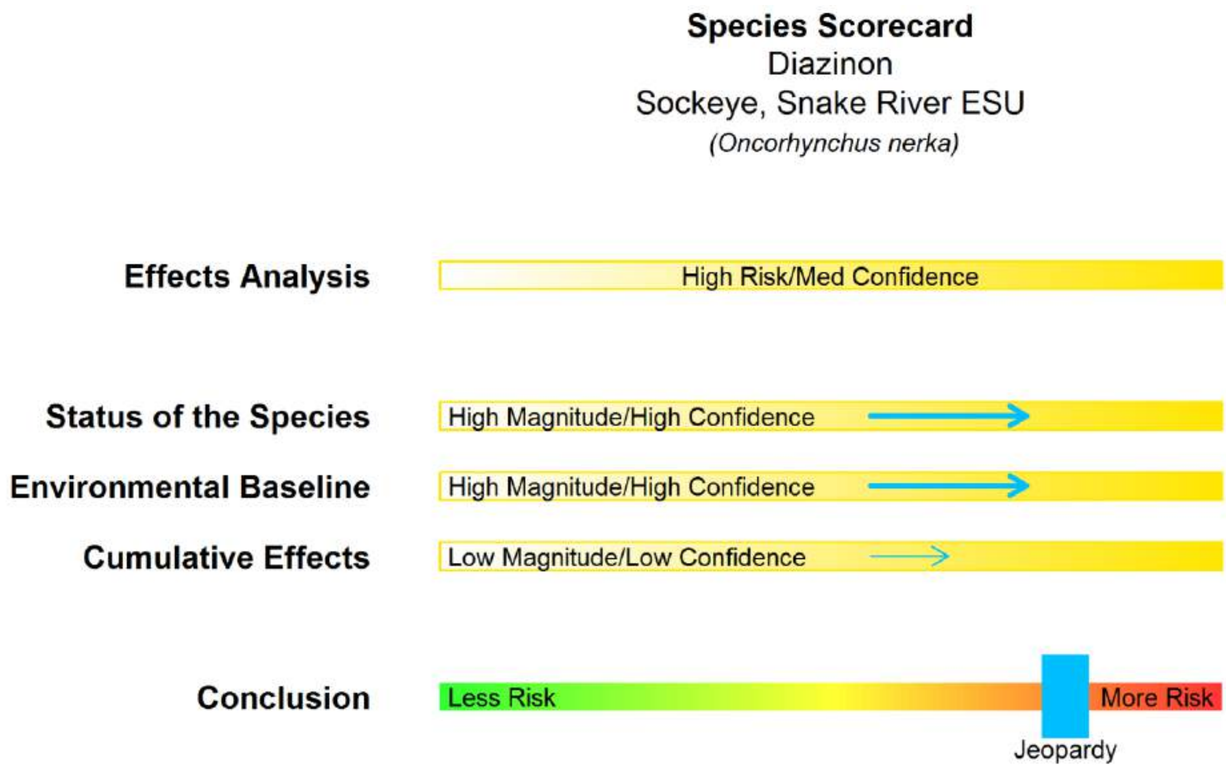

Figure 20. Species Score Card; Sockeye, Snake River ESU; Diazinon

Effects Analysis: High risk/Medium confidence

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- One population remaining supported by hatchery propagation. Increasing abundance, well below sustainable natural production. Low resilience to perturbations.
- Endangered (abundance only 1% of historical levels)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find medium confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species juvenile stage is most at risk while in freshwater areas. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Diazinon is likely to jeopardize the continued existence of this species: Jeopardy

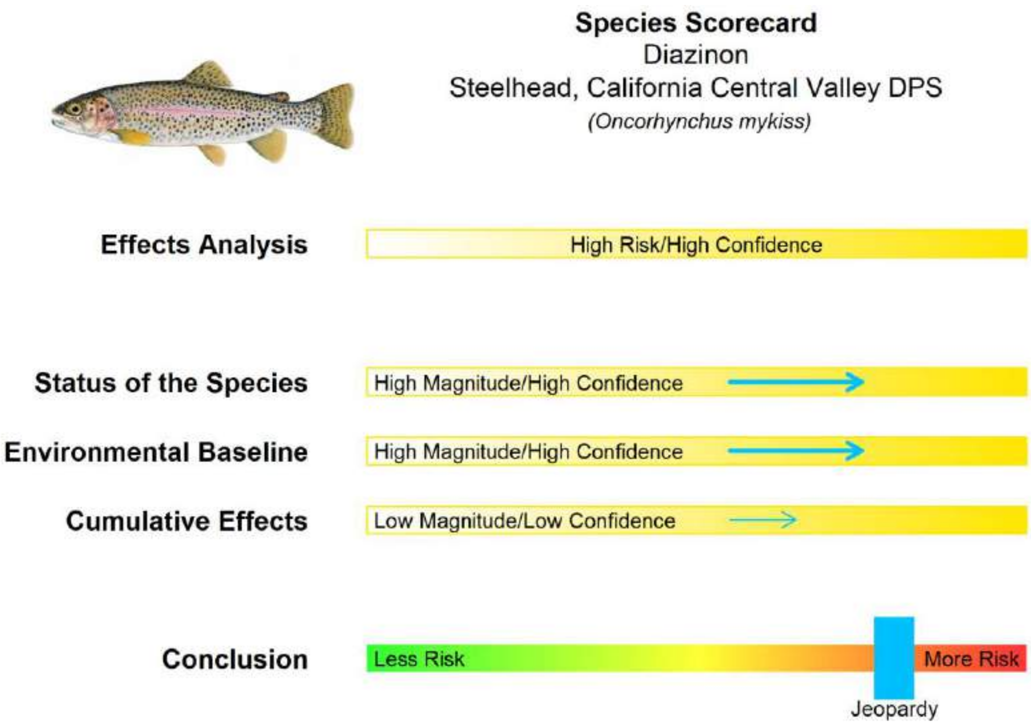

Figure 21. Species Score Card; Steelhead, California Central Valley Distinct Population Segment (DPS); Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Long-term trend of declining abundances and reduced genetic diversity. Populations supplemented by hatchery propagation.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

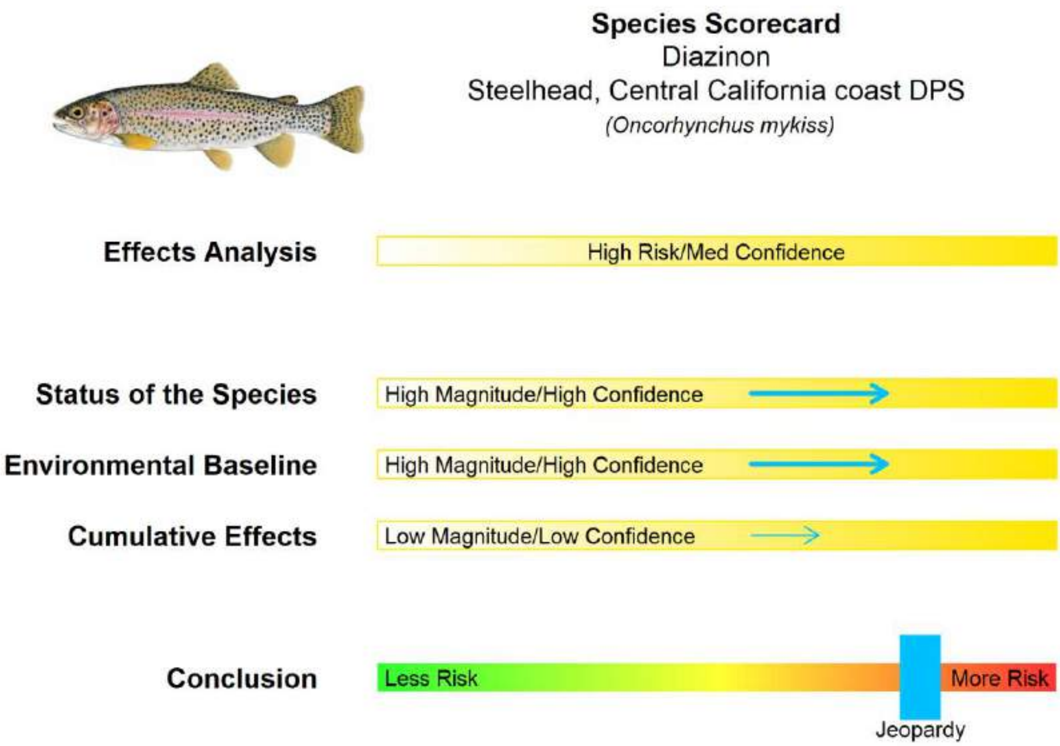

Figure 22. Species Score Card; Steelhead, Central California coast DPS; Diazinon

<u>Effects Analysis: High risk/Medium confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend uncertain. Population abundance supplemented by hatchery propagation. Populations likely not viable, and have lost spatial structure.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find medium confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

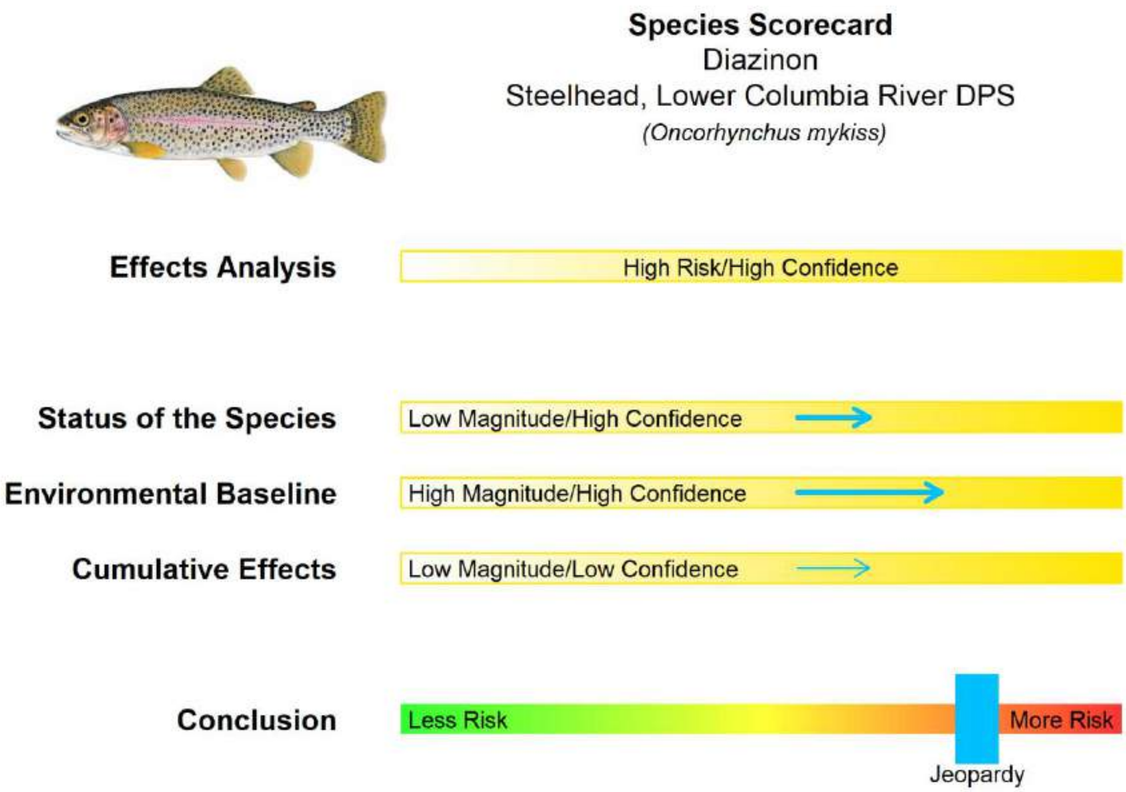

Figure 23. Species Score Card; Steelhead, Lower Columbia River DPS; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence</u>

- 5-year population trend stable. Populations exhibit low genetic diversity and impacted by a loss of available habitat.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Diazinon is likely to jeopardize the continued existence of this species: Jeopardy**</u>

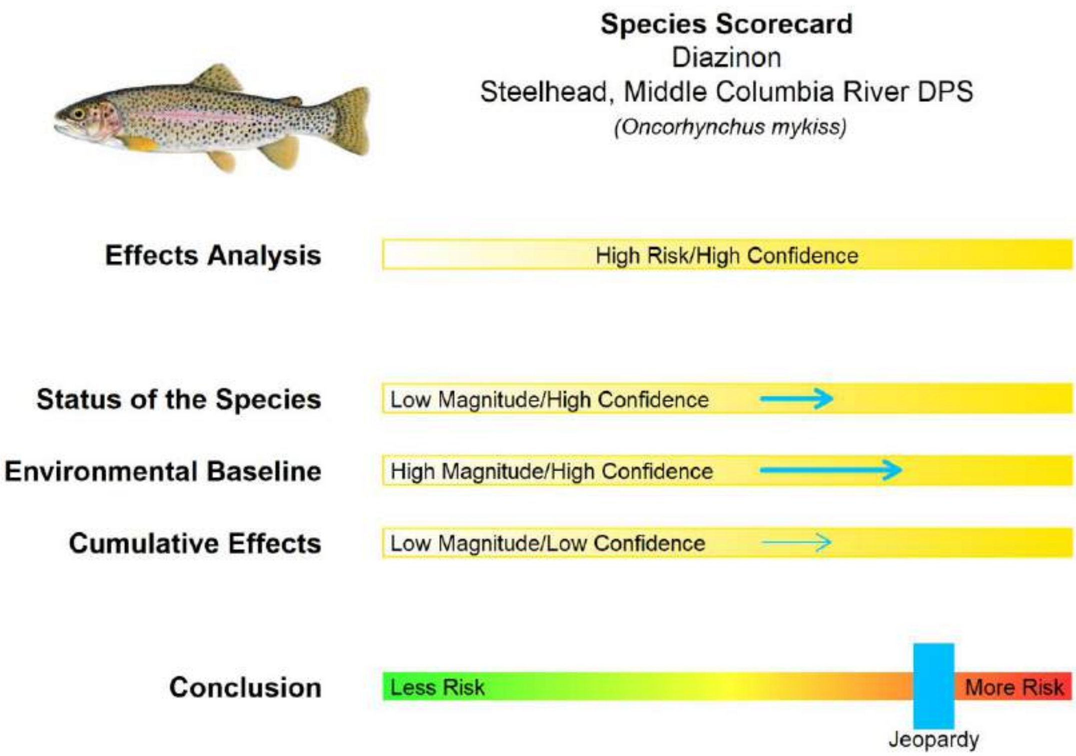

Figure 24. Species Score Card; Steelhead, Middle Columbia River DPS; Diazinon

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- 5-year population trend stable to improving; abundances remain low compared to historical numbers
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Diazinon is likely to jeopardize the continued existence of this species: Jeopardy

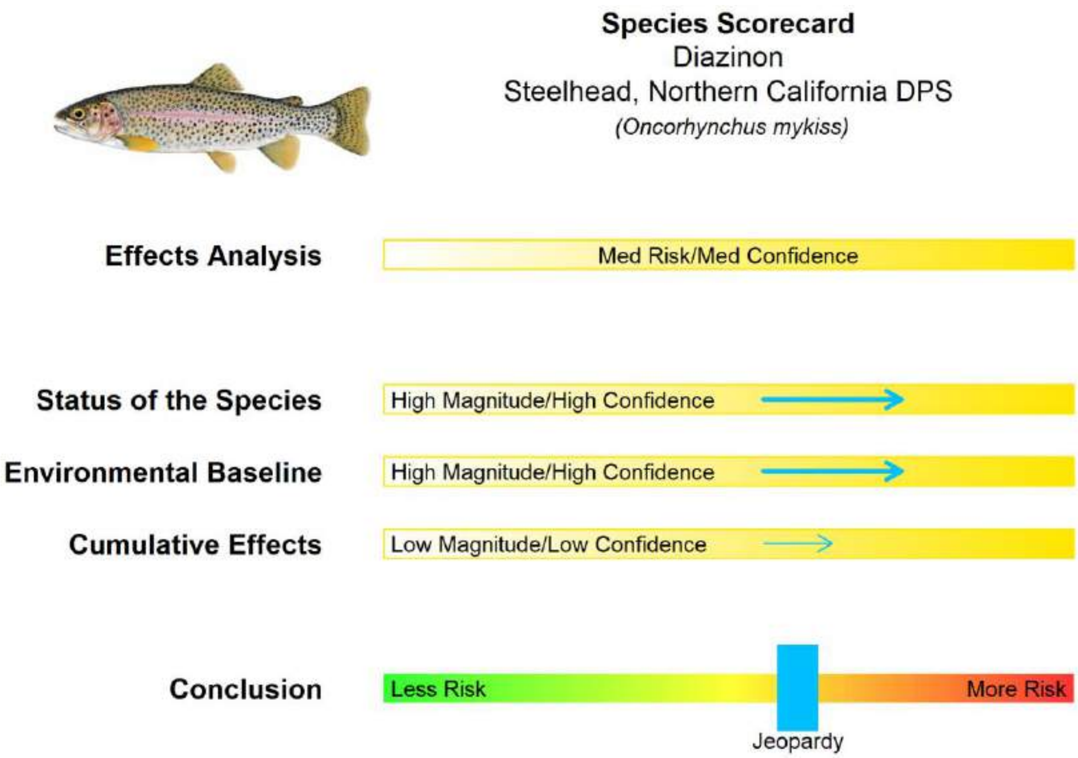

Figure 25. Species Score Card; Steelhead, Northern California DPS; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Icreased risk of jeopardy; High magnitude/ High confidence

- Variable 5-year population abundance trends; Population supplemented by hatchery propagation. Populations exhibit low abundances and productivity.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find medium confidence of medium risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Diazinon is likely to jeopardize the continued existence of this species: Jeopardy

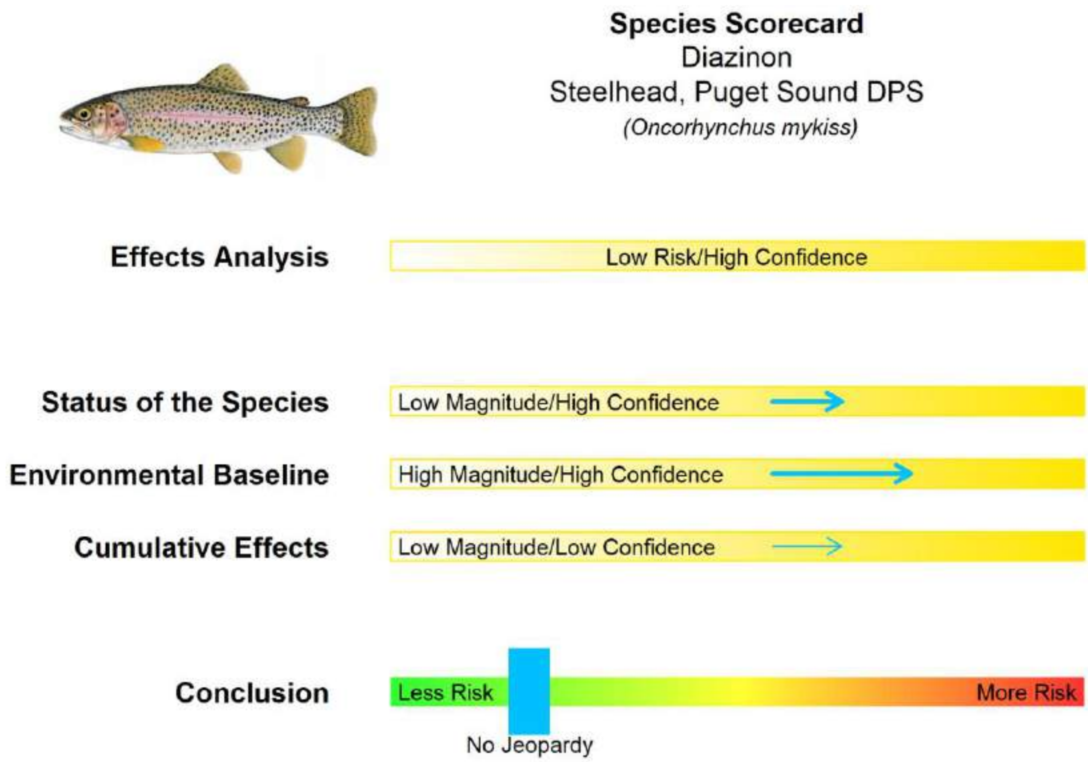

Figure 26. Species Score Card; Steelhead, Puget Sound DPS; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence</u>

- 5-year population trend stable, but populations have reduced genetic diversity
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

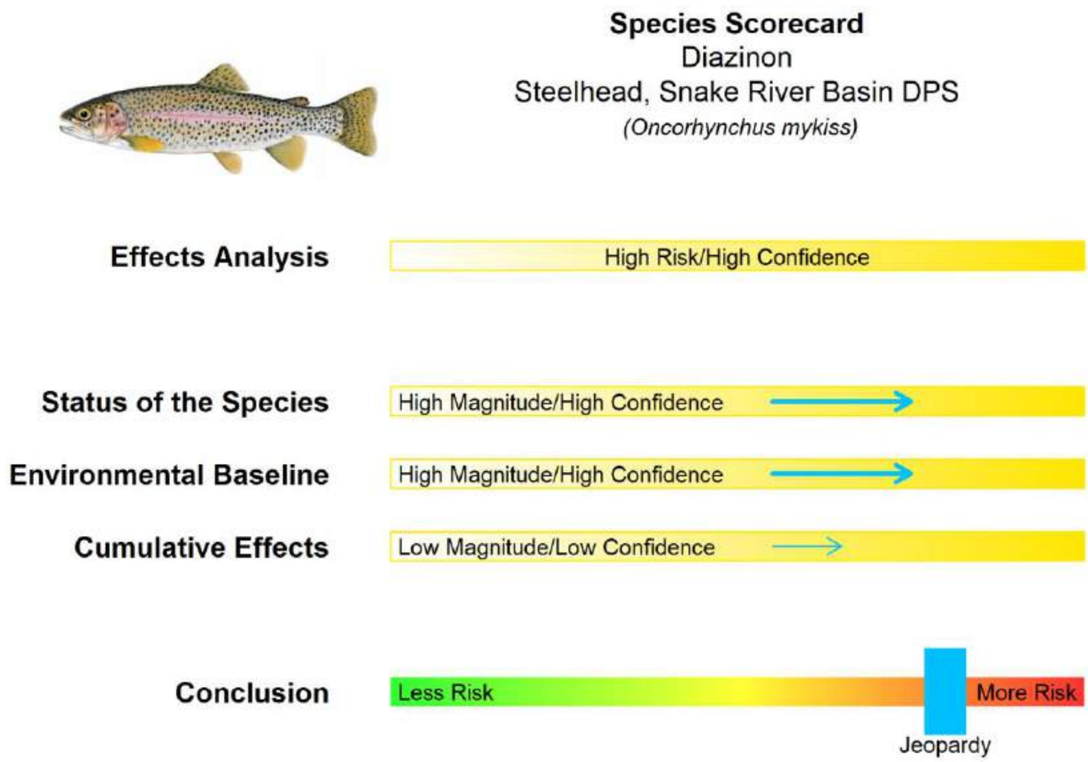

Figure 27. Species Score Card; Steelhead, Snake River Basin DPS; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend stable to improving, but still in moderate danger of extinction. Overall abundances remain below thresholds necessary for recovery.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

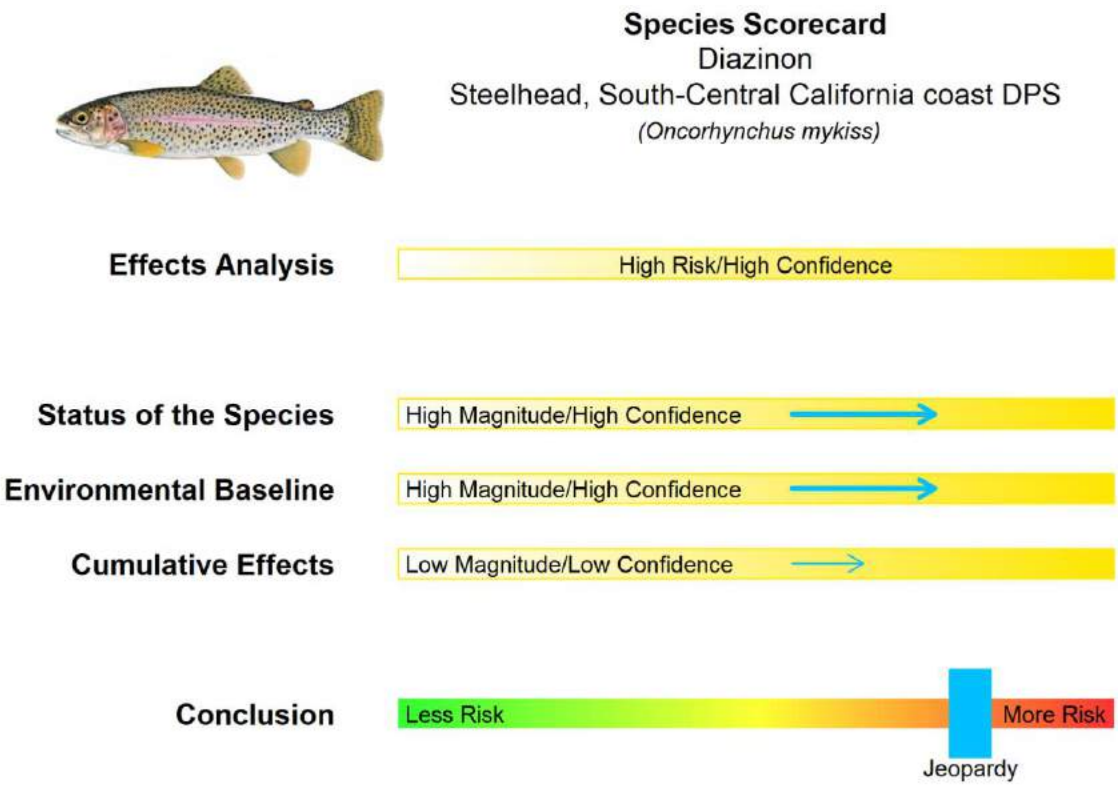

Figure 28. Species Score Card; Steelhead, South-Central California coast DPS; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend declining, depressed abundances.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

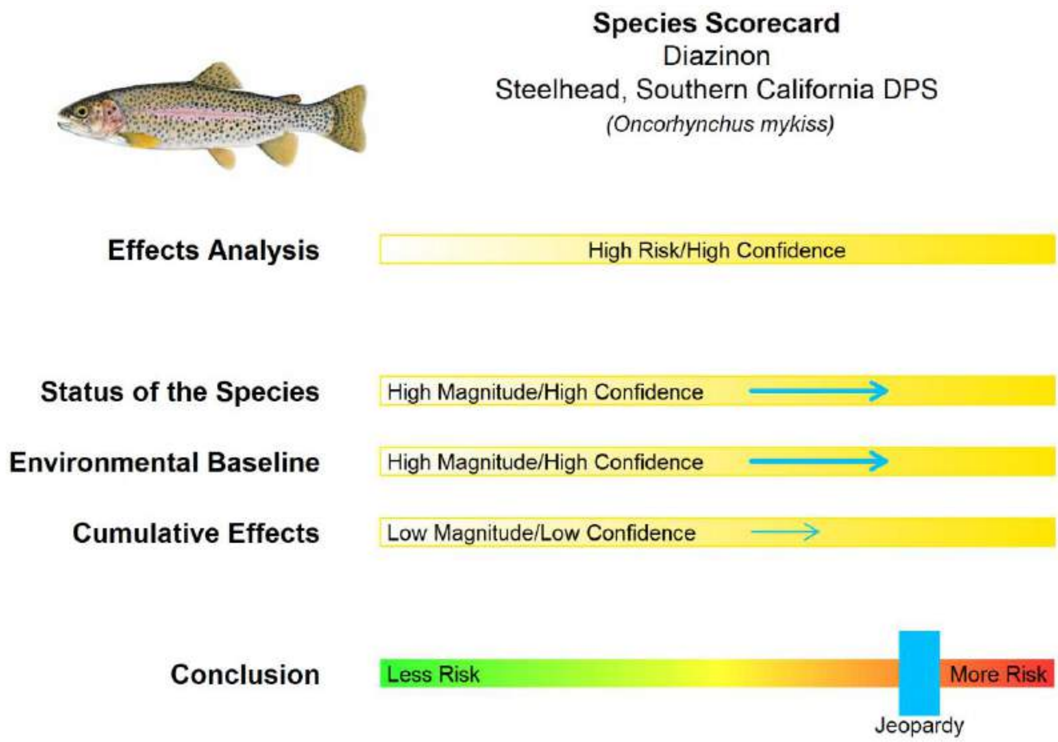

Figure 29. Species Score Card; Steelhead, Southern California DPS; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend uncertain (large annual variations); supplemented by hatchery propagation; fragmented distributions.
- Endangered; Populations at extreme southern end of species' range
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

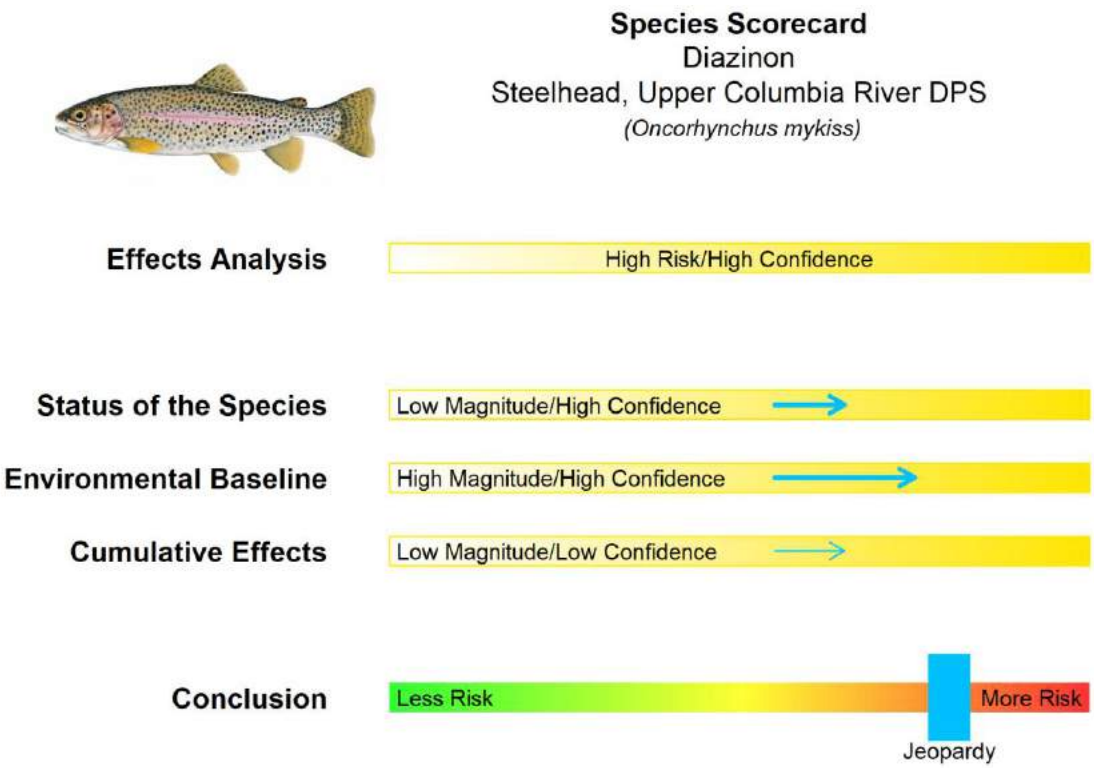

Figure 30. Species Score Card; Steelhead, Upper Columbia River DPS; Diazinon

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence

- 5-year population trend improving, but low genetic diversity.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Diazinon is likely to jeopardize the continued existence of this species: Jeopardy

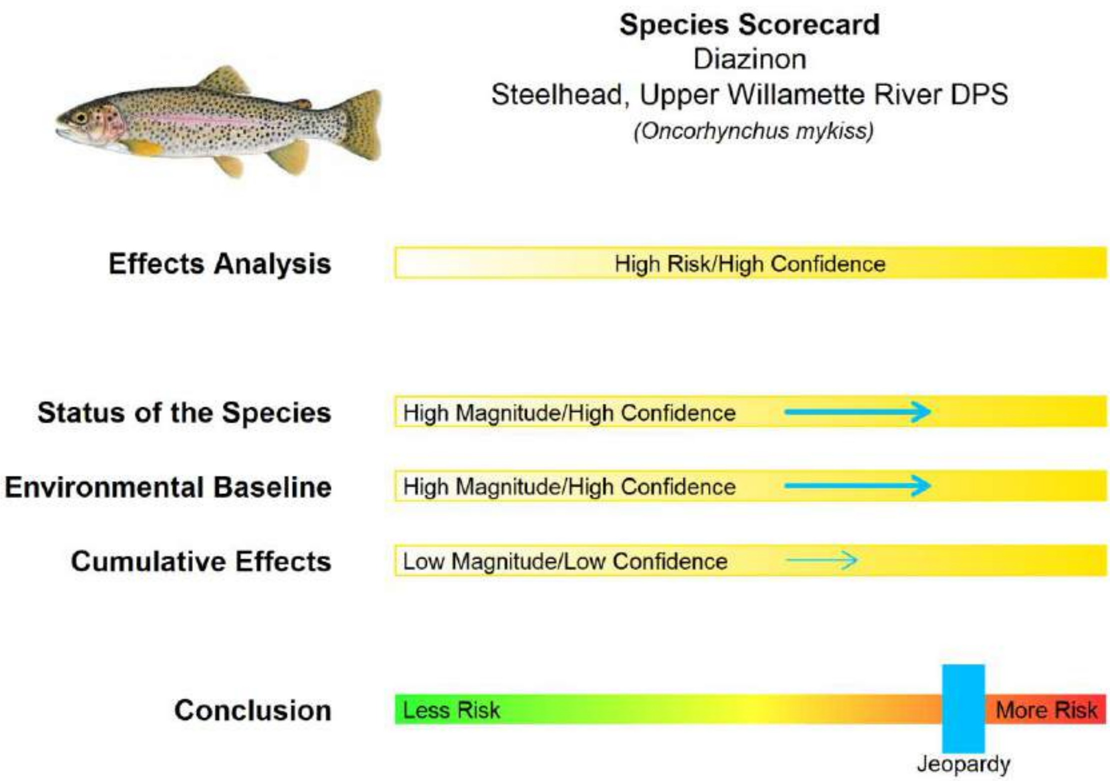

Figure 31. Species Score Card; Steelhead, Upper Willamette River DPS; Diazinon

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- 5-year population trend declining, large fluctuations in abundances.
- Threatened;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Diazinon is likely to jeopardize the continued existence of this species: Jeopardy

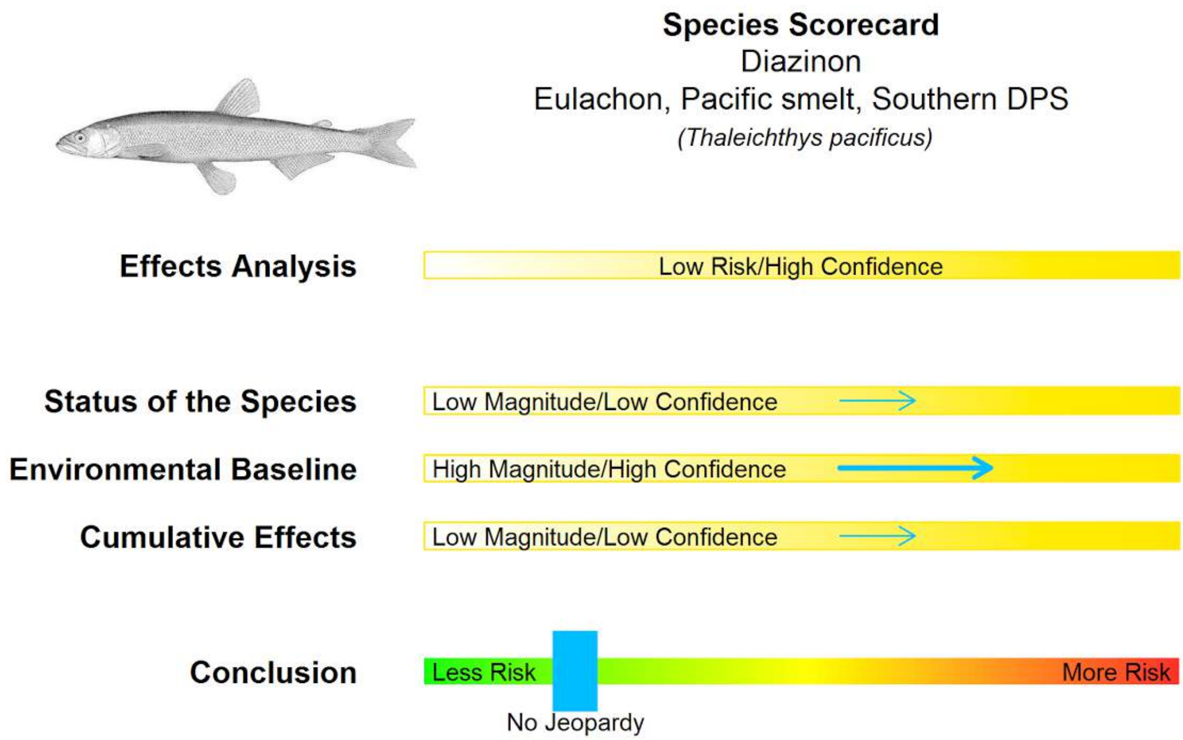

Figure 32. Species Score Card; Eulachon, Pacific smelt, Southern DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- Population abundance improving, especially in the 2013–2015 return years; in upcoming return years population declines may be widespread from poor ocean conditions
- Threatened; severely depressed abundance mid-late 1990s to late 2000s;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

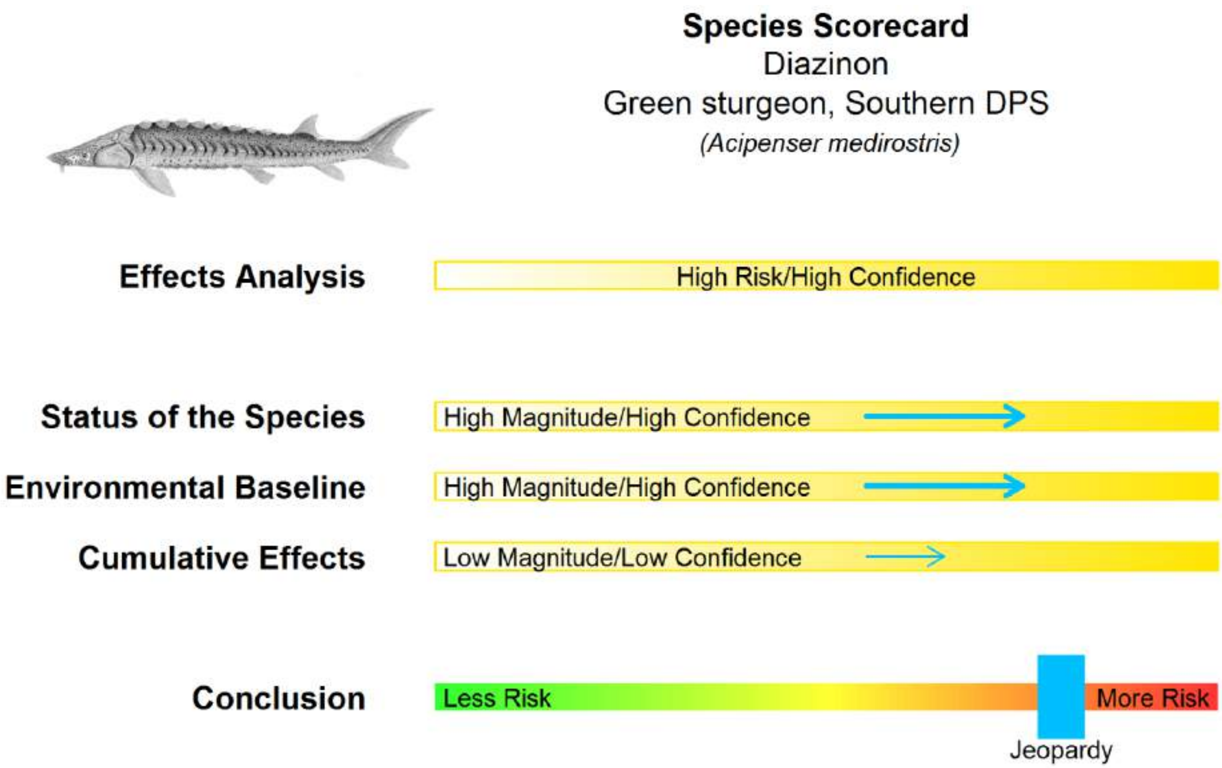

Figure 33. Species Score Card; Green sturgeon, Southern DPS; Diazinon

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Small population size, little population data, few remaining spawning sites
- Threatened;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Diazinon is likely to jeopardize the continued existence of this species: Jeopardy

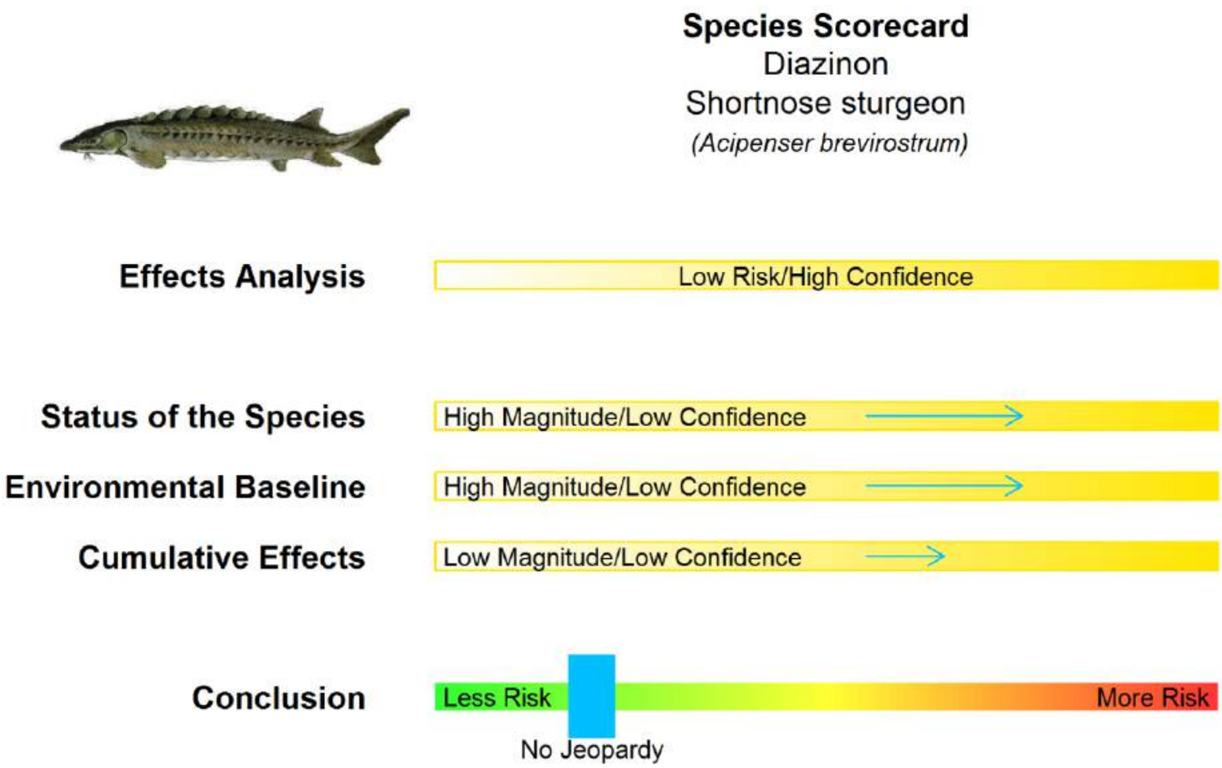

Figure 34. Species Score Card; Shortnose sturgeon; Diazinon

Effects Analysis: Low risk/High confidence

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence

- Stable to increasing populations, fragmented populations, only 12 known spawning sites
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

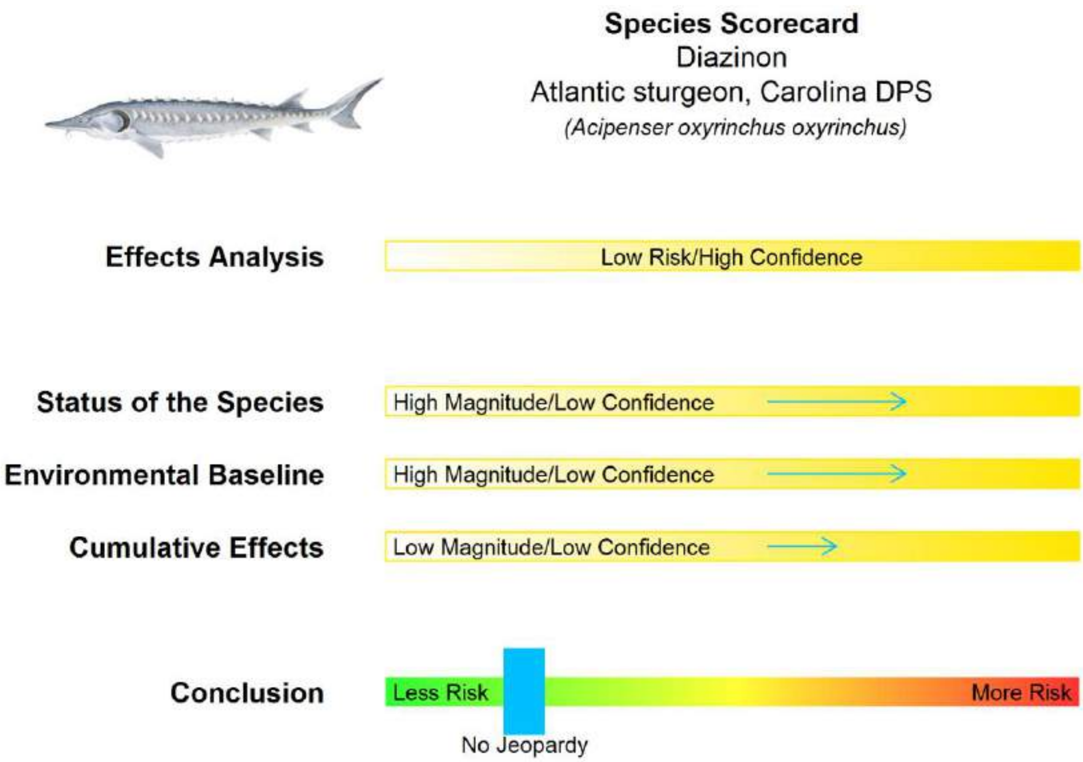

Figure 35. Species Score Card; Atlantic sturgeon, Carolina DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence

- <3% of historical abundance
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

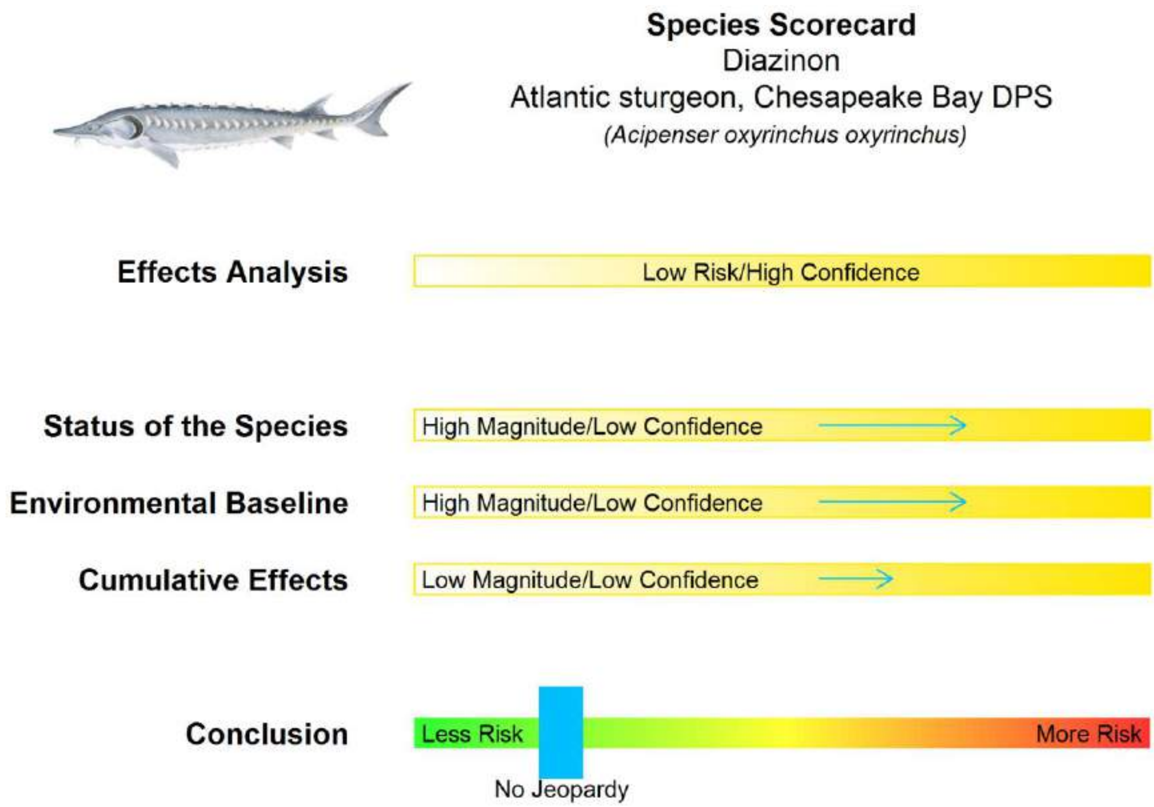

Figure 36. Species Score Card; Atlantic sturgeon, Chesapeake Bay DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence

- 4% of historical abundance, unknown population growth rate
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

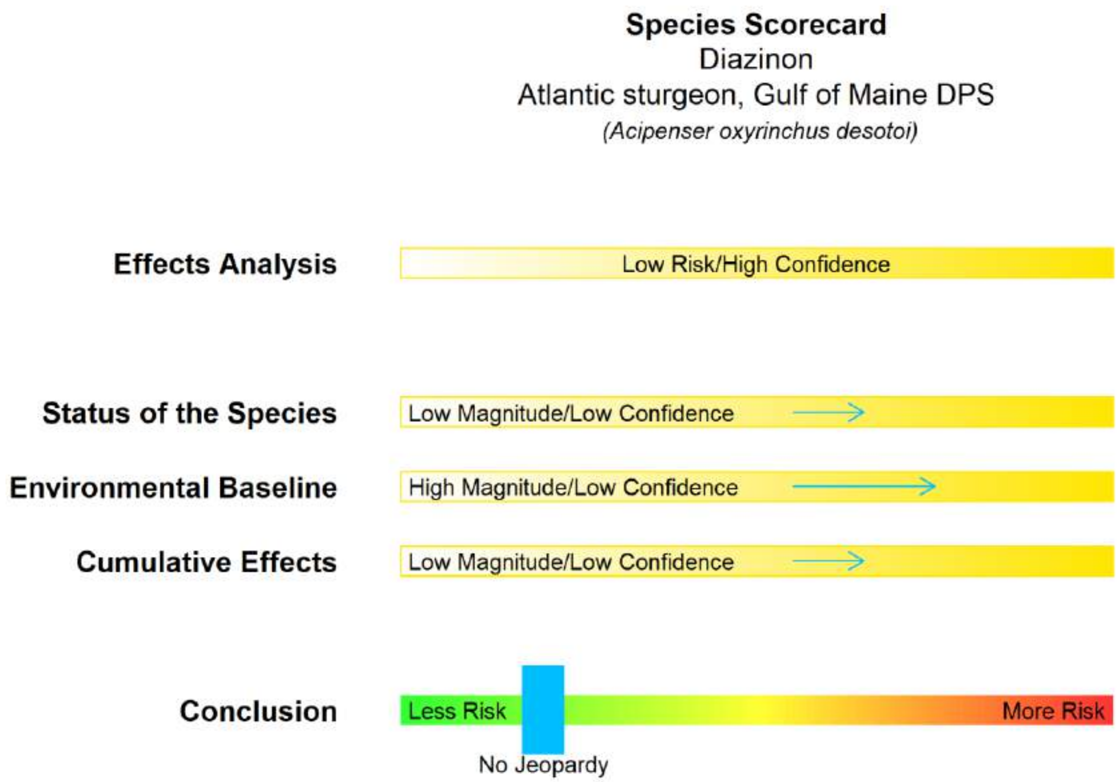

Figure 37. Species Score Card; Atlantic sturgeon, Gulf of Maine DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: minimal increased risk of jeopardy; Low magnitude/ low confidence

- 10% of historical abundance, unknown population growth rate, range expanding
- Threatened;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

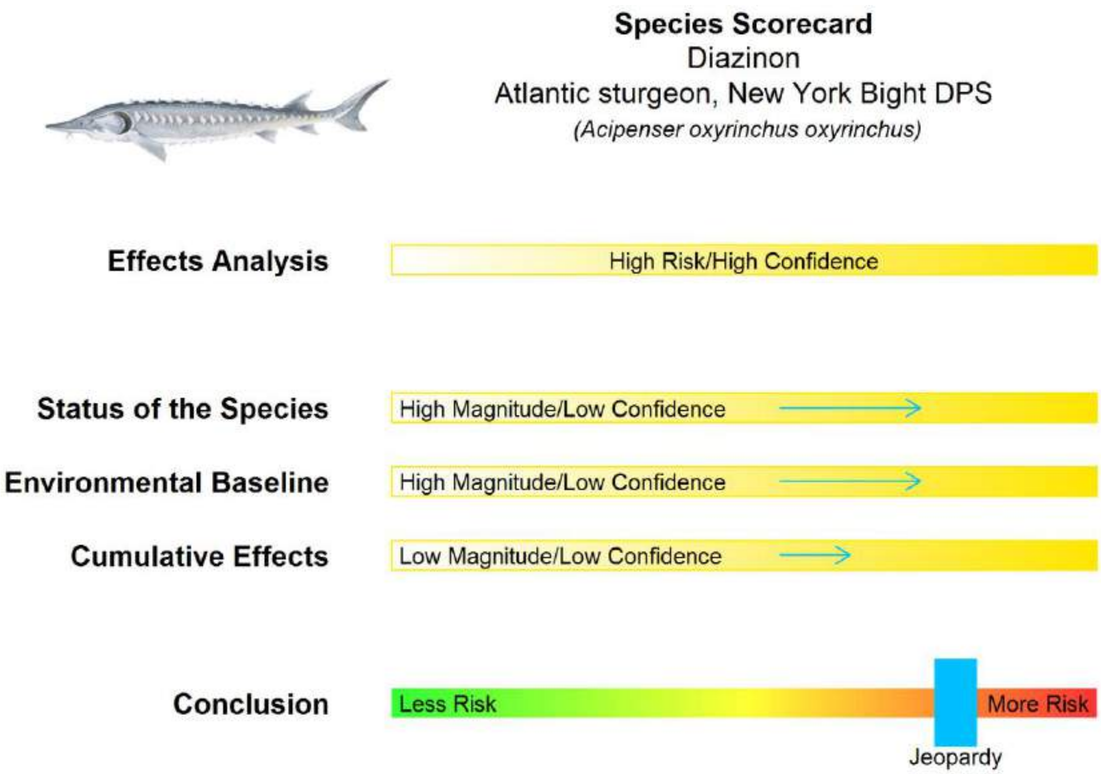

Figure 38. Species Score Card; Atlantic sturgeon, New York Bight DPS; Diazinon

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence</u>

- 4% of historical abundance, unknown population growth rate
- Endangered;
- Recovery criteria not identified

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

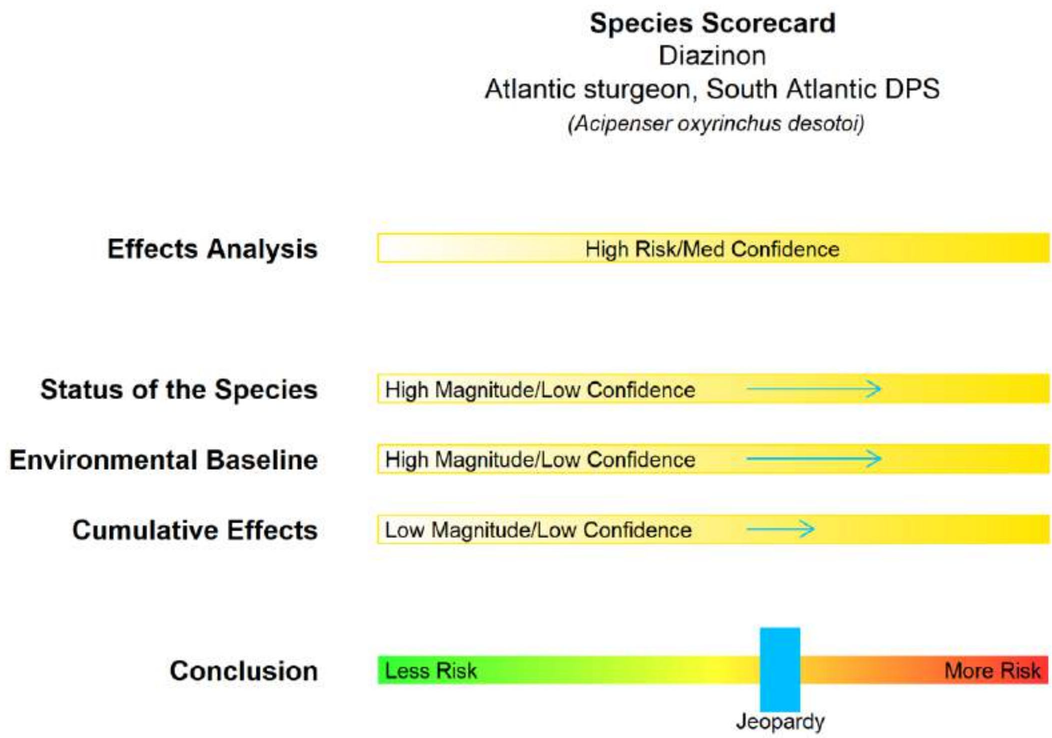

Figure 39. Species Score Card; Atlantic sturgeon, South Atlantic DPS; Diazinon

Effects Analysis: High risk/Medium confidence

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence

- <6% of historical abundance
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find medium confidence of high risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Diazinon is likely to jeopardize the continued existence of this species: Jeopardy

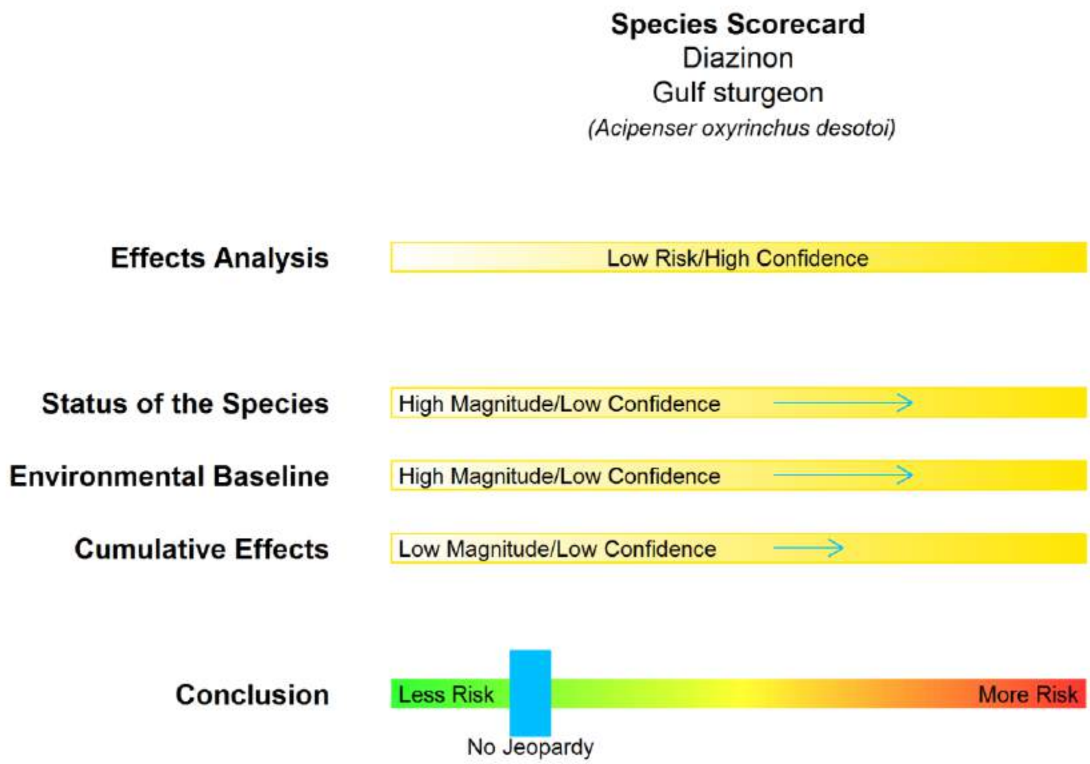

Figure 40. Species Score Card; Gulf sturgeon; Diazinon

Effects Analysis: Low risk/High confidence

- Significant reductions in abundance or productivity not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Eastern range populations stable to increasing, western population lower abundances and more uncertainty, minimal growth rate data
- Threatened
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated to affect species
- Anticipated hydrologic effects in freshwater areas

Conclusion: We find high confidence of low risk to the species based on predicted freshwater exposure concentrations and expected population-level effects. The species is most at risk while in freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

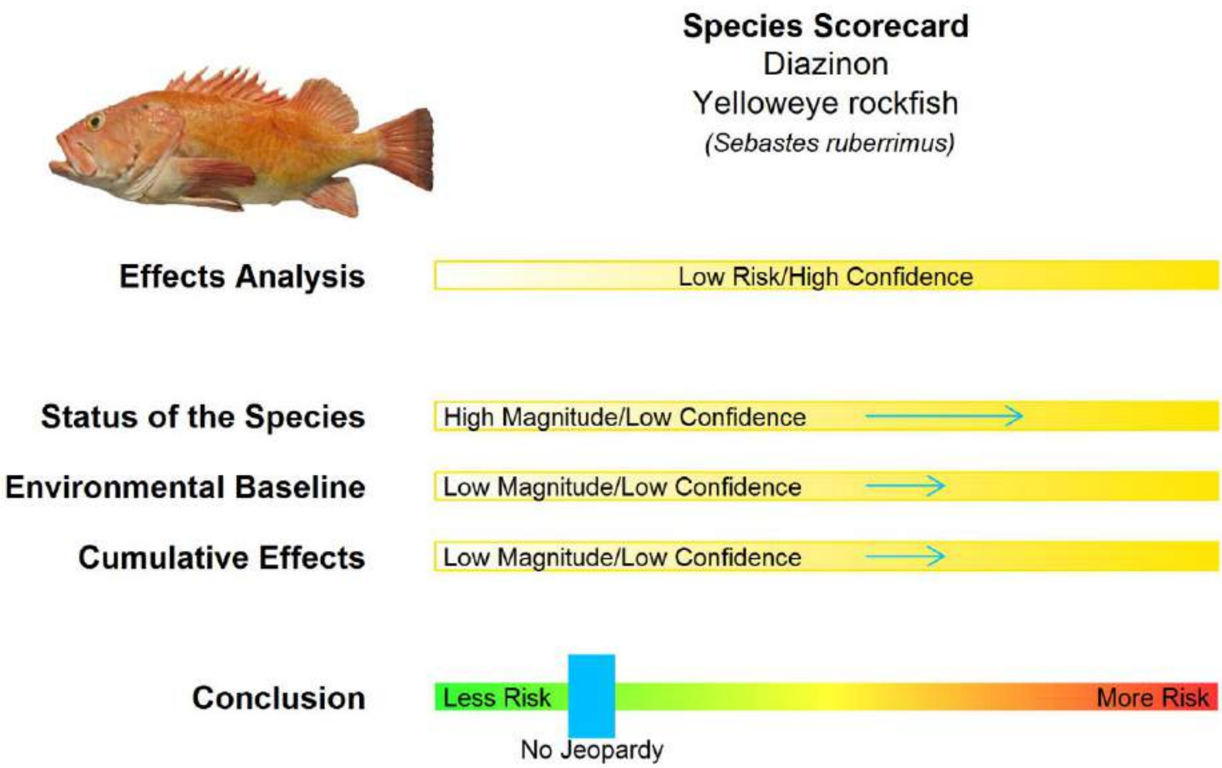

Figure 41. Species Score Card; Yelloweye rockfish; Diazinon

Effects Analysis: Low risk/High confidence

- Reduced abundance and productivity of adults in deeper marine waters not anticipated
- Exposure to mixtures expected to enhance toxicity
- Uncertain exposure concentrations in marine waters

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Historically low abundance, fragmented populations, altered population age structure
- Threatened
- Recovery criteria not identified

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures not anticipated in marine waters
- Environmental mixtures at toxic concentrations not anticipated in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated

Conclusion: We find high confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in deep marine habitats where this species resides. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

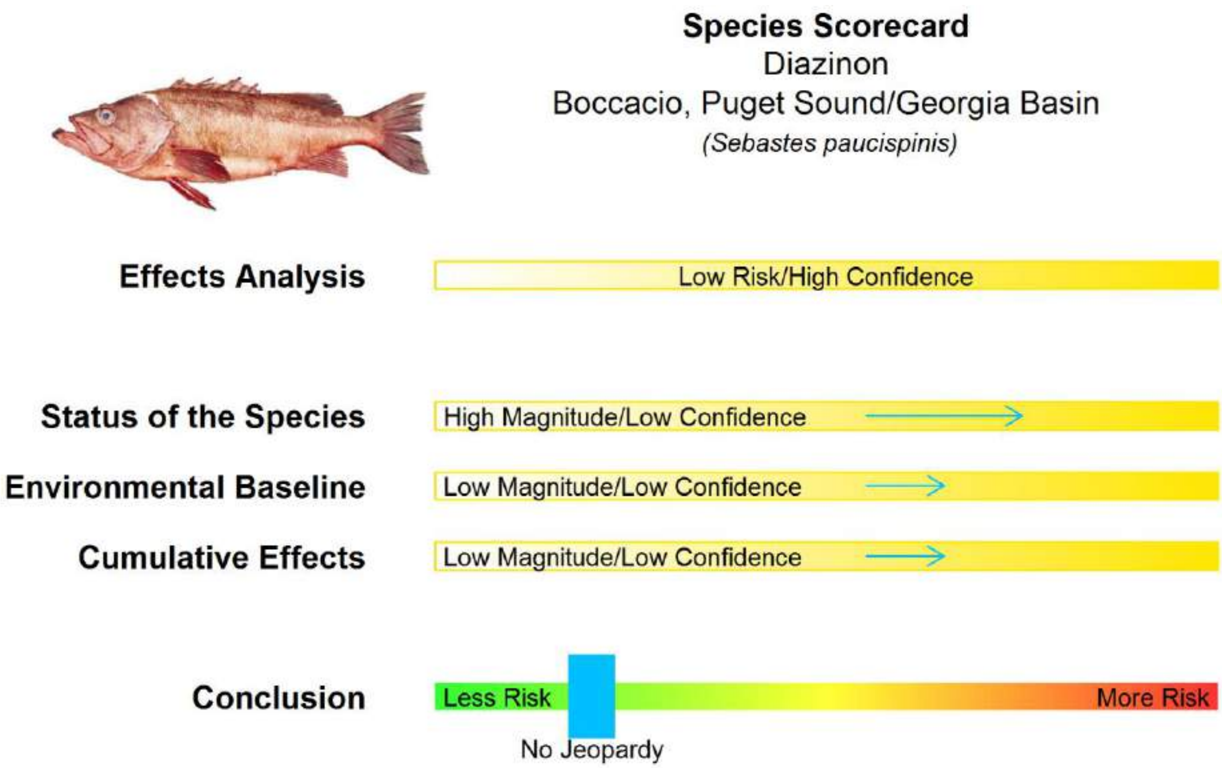

Figure 42. Species Score Card; Boccacio, Puget Sound/Georgia Basin; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Reduced abundance and productivity of adults in deeper marine waters not anticipated
- Exposure to mixtures expected to enhance toxicity
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- There are no estimates of historical or current abundance across the DPS's full range; Indices suggest declining abundance trends
- Threatened
- Recovery criteria not identified

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated in marine waters

<u>Conclusion:</u> We find high confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in deep marine habitats where this species resides. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>**Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy**</u>

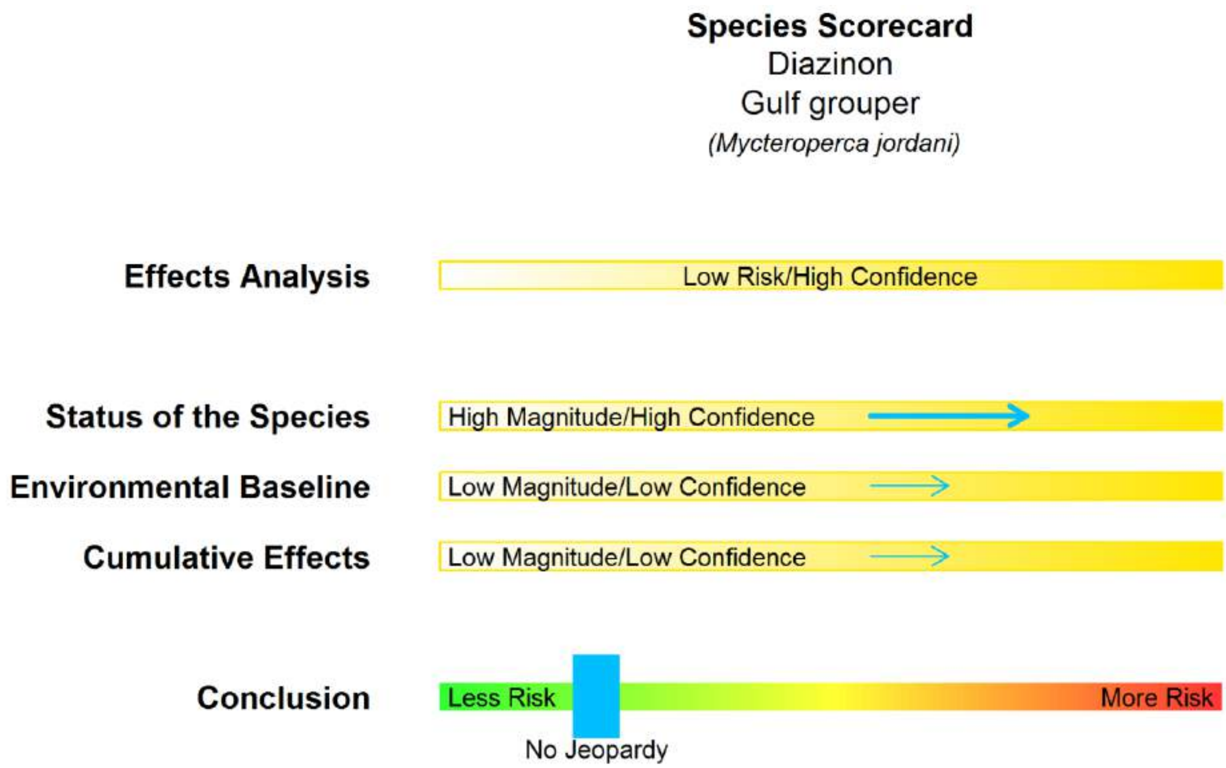

Figure 43. Species Score Card; Gulf grouper; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Reduced abundance and productivity of adults in deeper marine waters not anticipated
- Exposure to mixtures expected to enhance toxicity
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Abundance levels less than 1% of their historical levels
- Endangered
- Recovery criteria not identified

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated in marine waters

<u>Conclusion:</u> We find high confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in deep marine habitats where this species resides. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

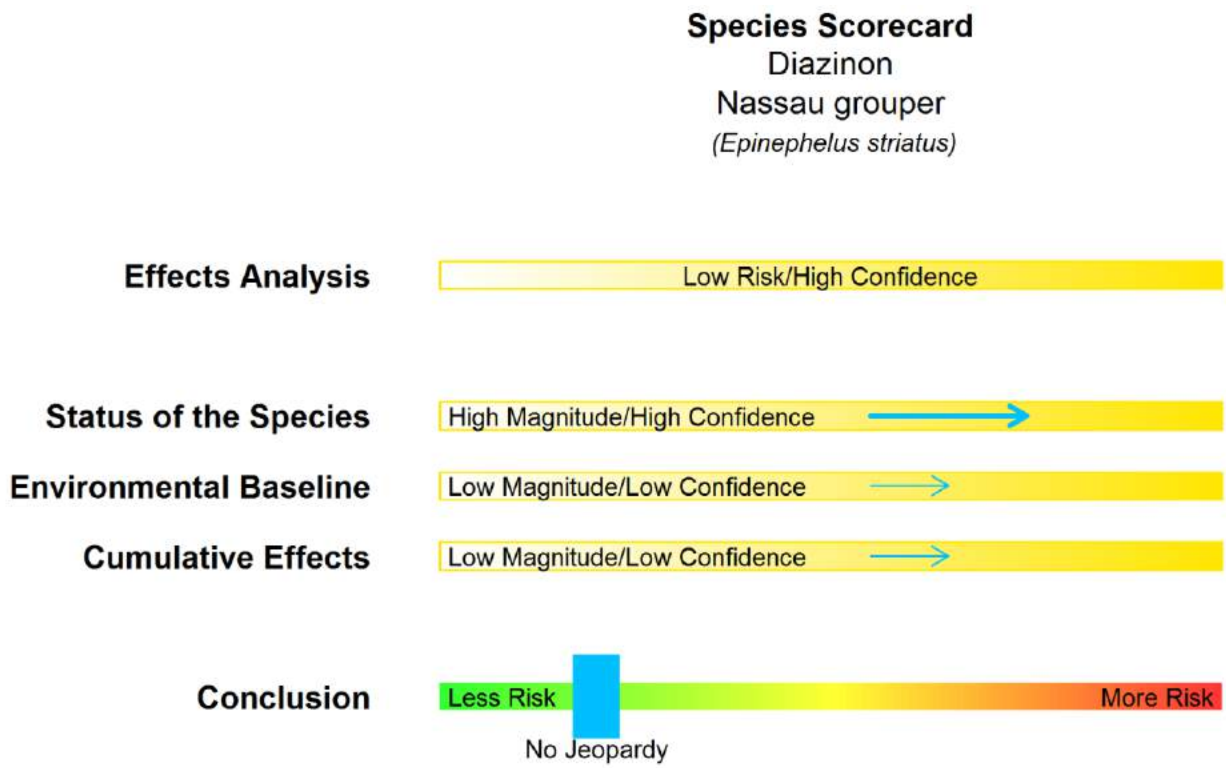

Figure 44. Species Score Card; Nassau grouper; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Reduced abundance and productivity of adults in deeper marine waters not anticipated
- Exposure to mixtures expected to enhance toxicity
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- The species has pathcy abundance with declining abundance trends. Throughout its range reductions in the size and number of spawning aggregations;
- Threatened
- Recovery criteria not identified

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures not anticipated at toxic concentrations in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated in marine waters

<u>Conclusion:</u> We find high confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in deep marine habitats where this species resides. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

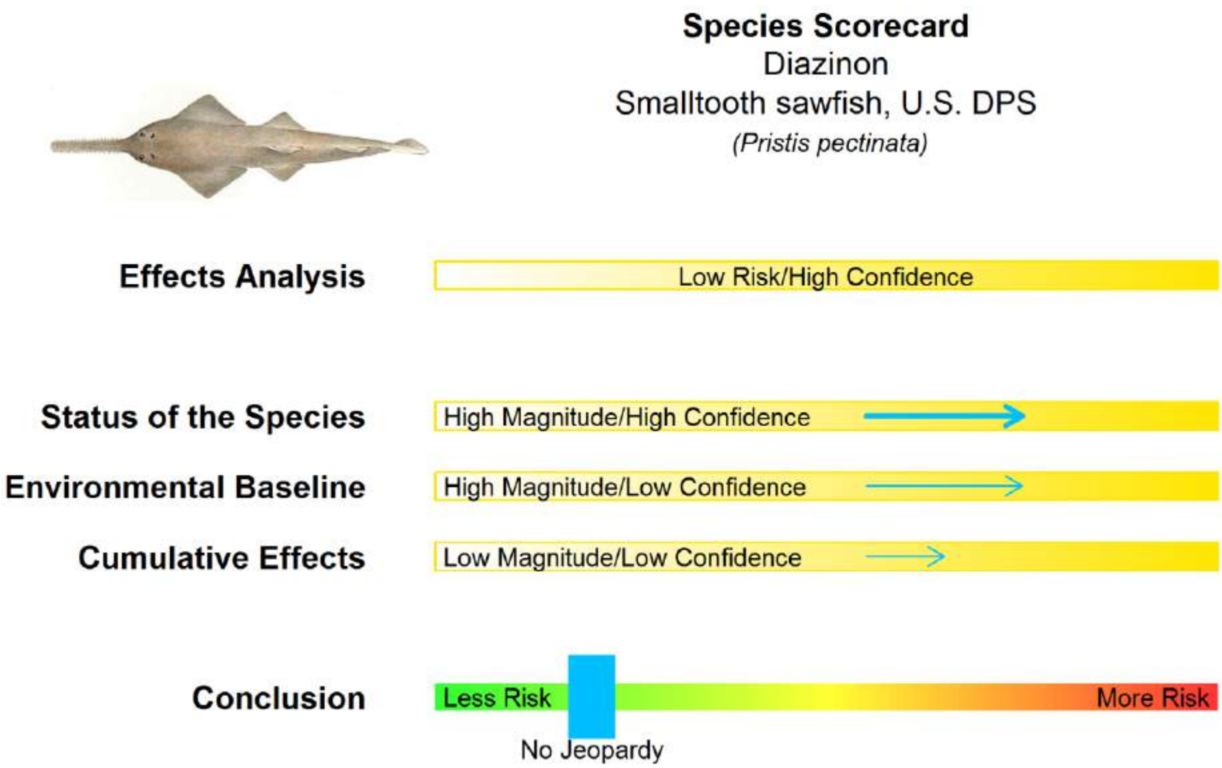

Figure 45. Species Score Card; Smalltooth sawfish, U.S. DPS; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Reduced abundance and productivity of adults in deeper marine waters not anticipated
- Exposure to mixtures expected to enhance toxicity
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Stable abundance, low population growth rates, <5% of historical abundance
- Endangered
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> We find high confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in deep marine habitats where this species resides. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

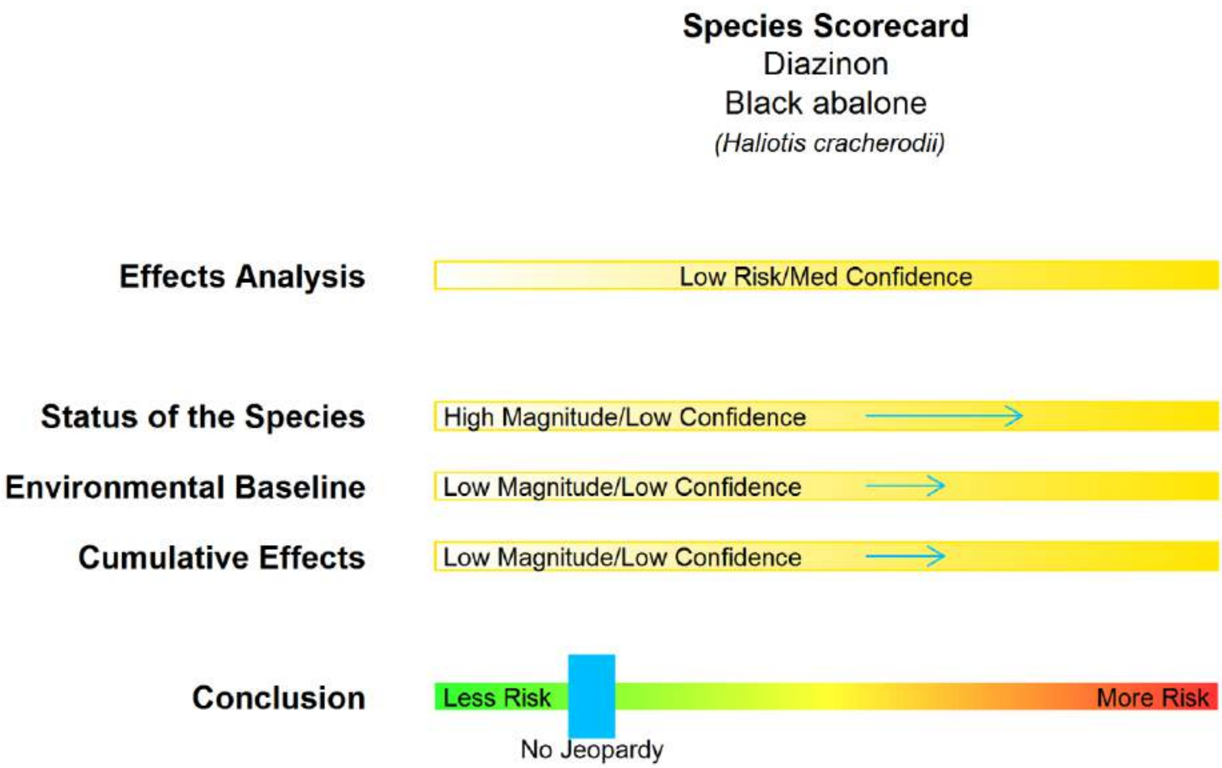

Figure 46. Species Score Card; Black abalone; Diazinon

Effects Analysis: Low risk/Medium confidence

- Reduced abundance and productivity not anticipated in marine areas
- Uncertain exposure concentrations in coastal and marine habitats
- Impacts may occur to individuals occupying shallow tidepools

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- 5% of historical abundance, declining population trend
- Endangered
- Recovery criteria not identified

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated in marine waters

Conclusion: We find medium confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in tidepools and marine habitats where this species resides. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

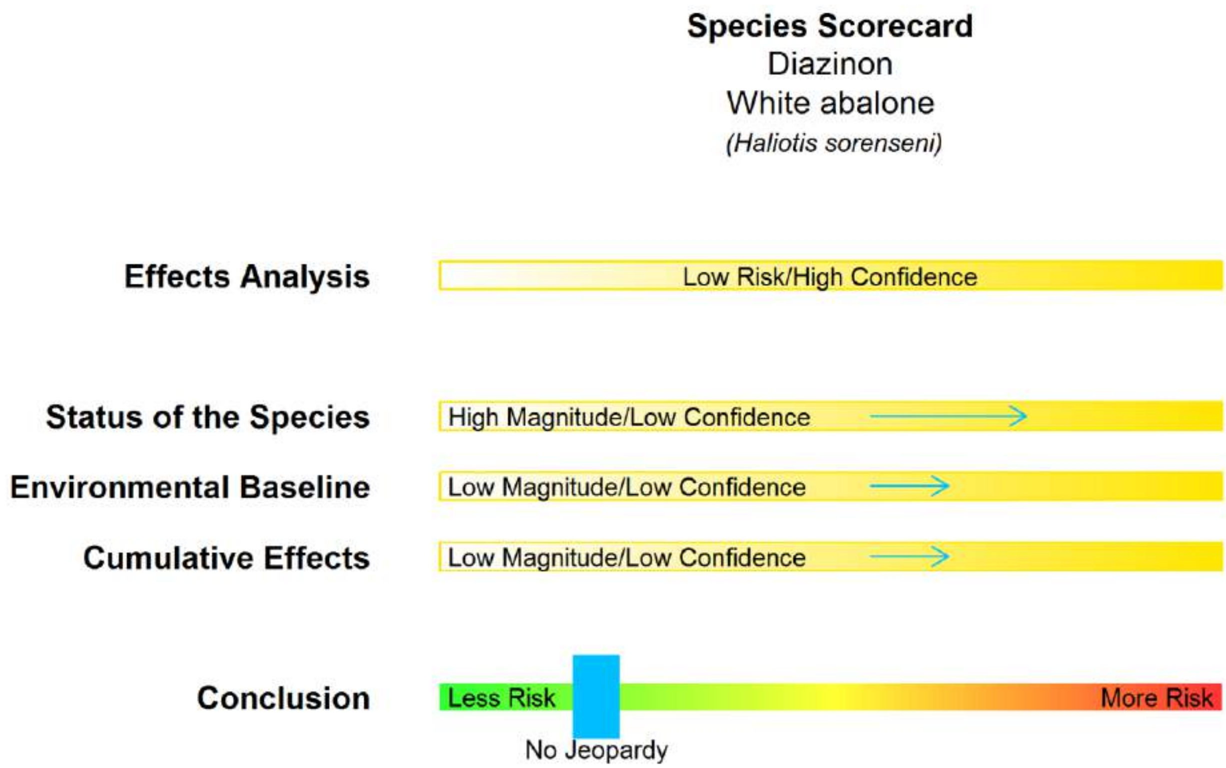

Figure 47. Species Score Card; White abalone; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Reduced abundance and productivity not anticipated in marine areas
- Uncertain exposure concentrations in deep marine habitats

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Declining population trend, lack of recruitment, no current estimated population size
- Endangered;
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated in marine waters

<u>Conclusion:</u> We find high confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in deep marine habitats where adults and juveniles reside. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

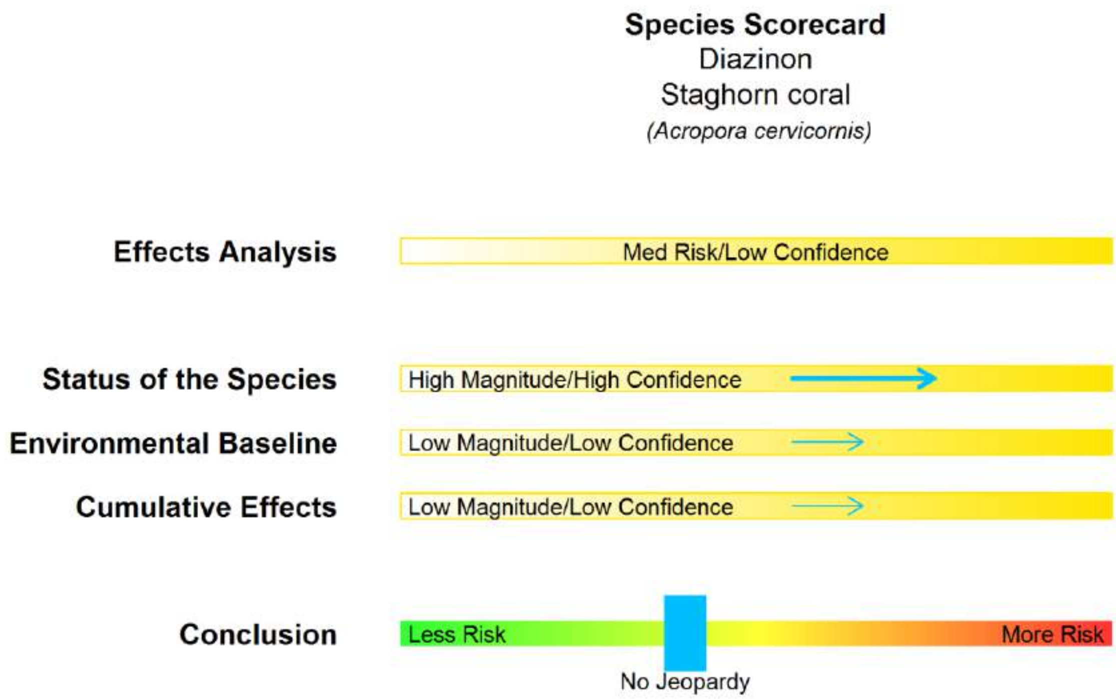

Figure 48. Species Score Card; Staghorn coral; Diazinon

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Severe reductions in abundance in portions of range; populations remain stable at depressed levels
- Threatened
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats. A maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

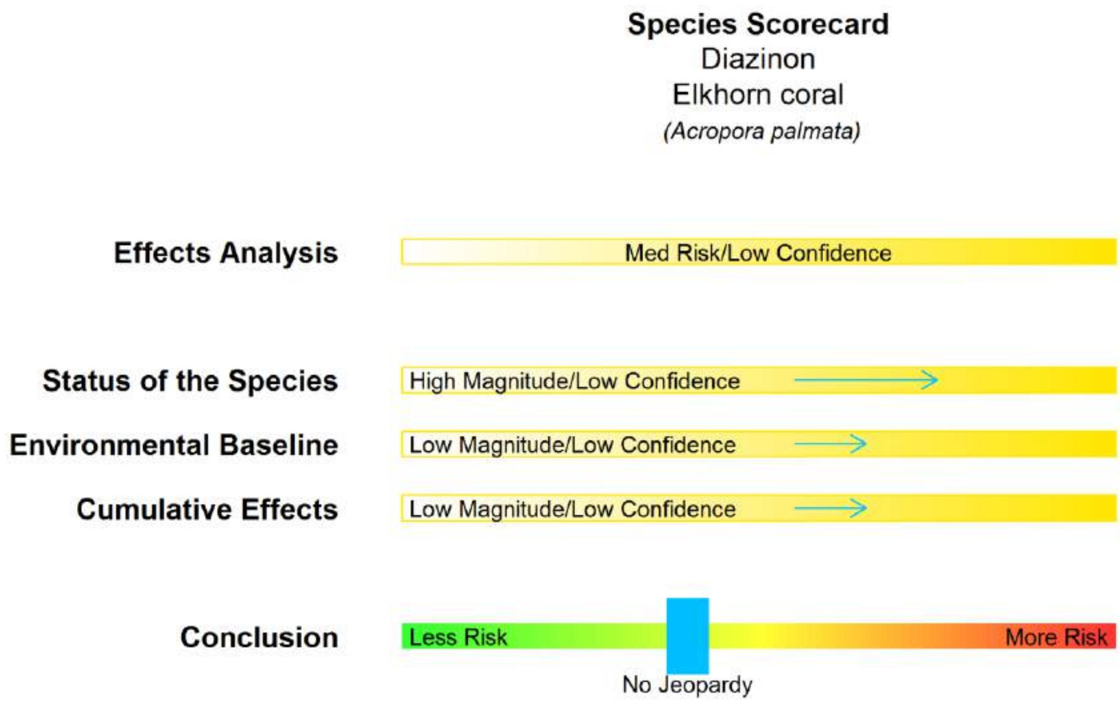

Figure 49. Species Score Card; Elkhorn coral; Diazinon

Effects Analysis: Medium risk/Low confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Low abundance, large declines over past decades. Genetically depauparate populations in Caribbean. In eastern Caribbean, population is doing better and is genetically richer.
- Threatened
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats. A maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

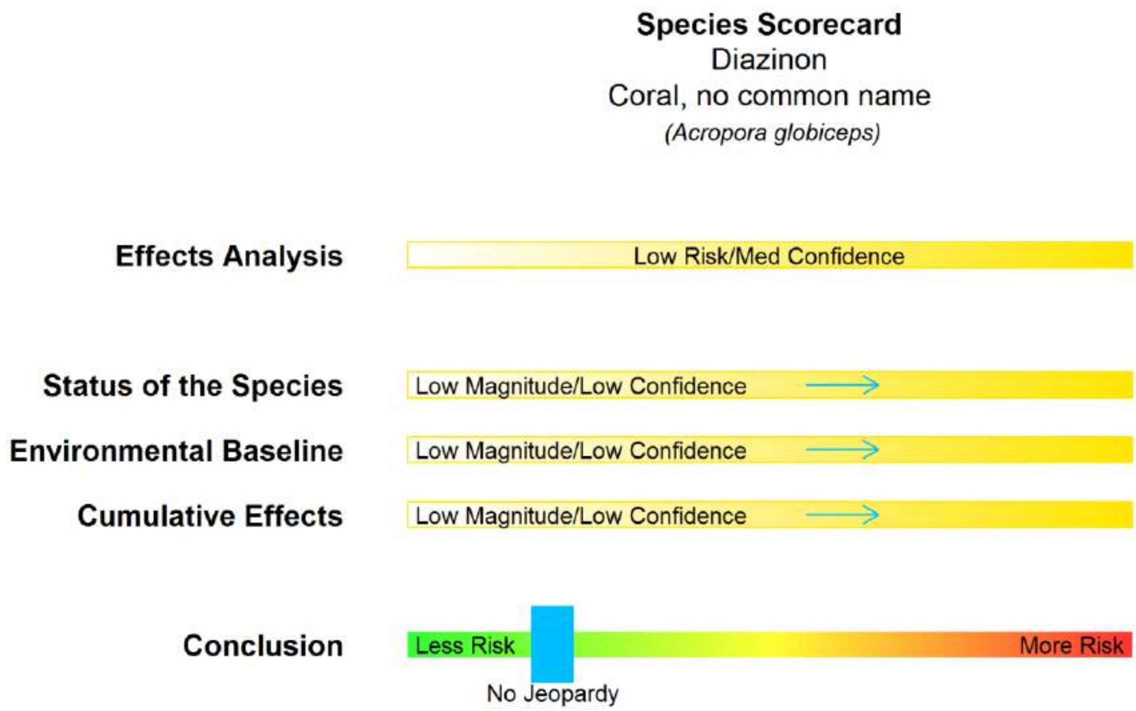

Figure 50. Species Score Card; Coral, Acropora globiceps; Diazinon

<u>Effects Analysis: Low risk/Medium confidence</u>

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Range is extensive throughout the Indo-Pacific region; less than 5% of the population is within the action area; overall status and growth rates unknown
- Threatened
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats. About 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

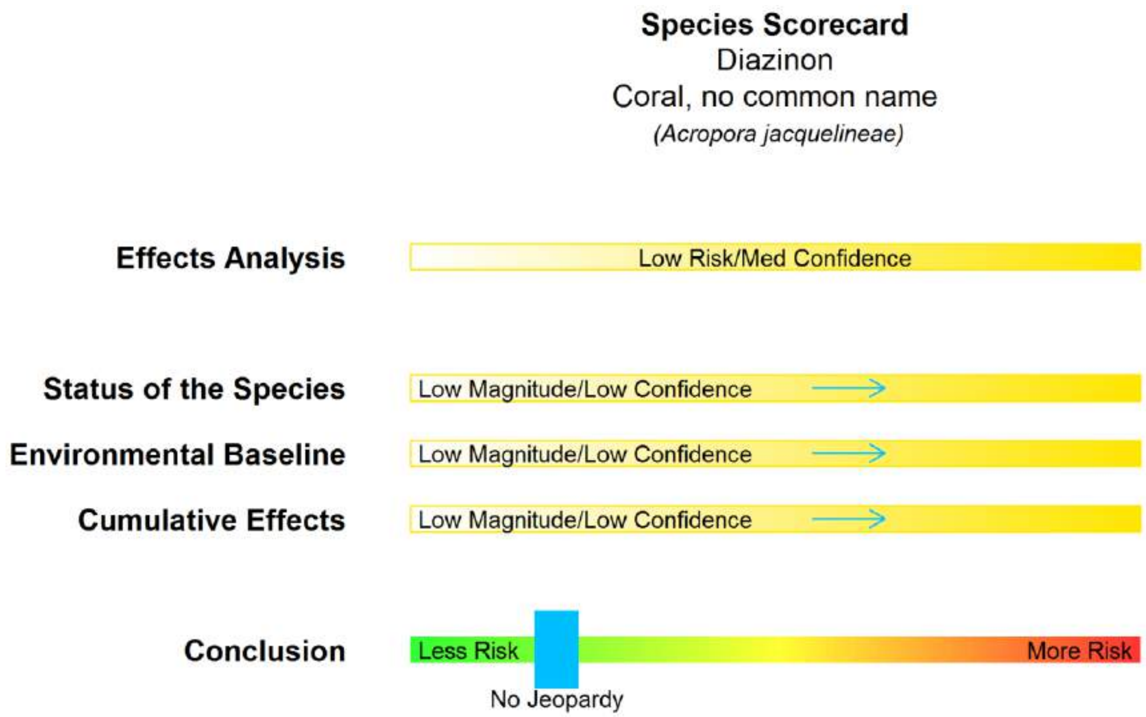

Figure 51. Species Score Card; Coral, Acropora jacquelineae; Diazinon

Effects Analysis: Low risk/Medium confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region; less than 5% of the population is within the action area; overall status and growth rates unknown
- Threatened
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats. About 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

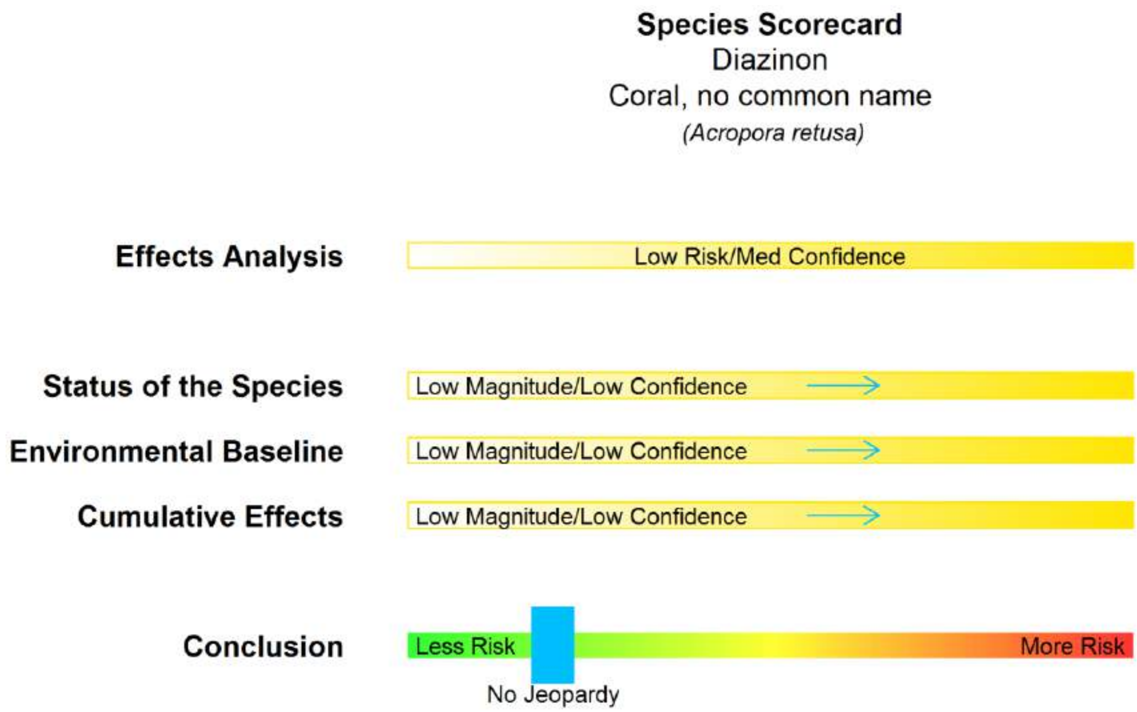

Figure 52. Species Score Card; Coral, Acropora retusa; Diazinon

Effects Analysis: Low risk/Medium confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region; less than 5% of the population is within the action area; overall status and growth rates unknown
- Threatened
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats. About 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

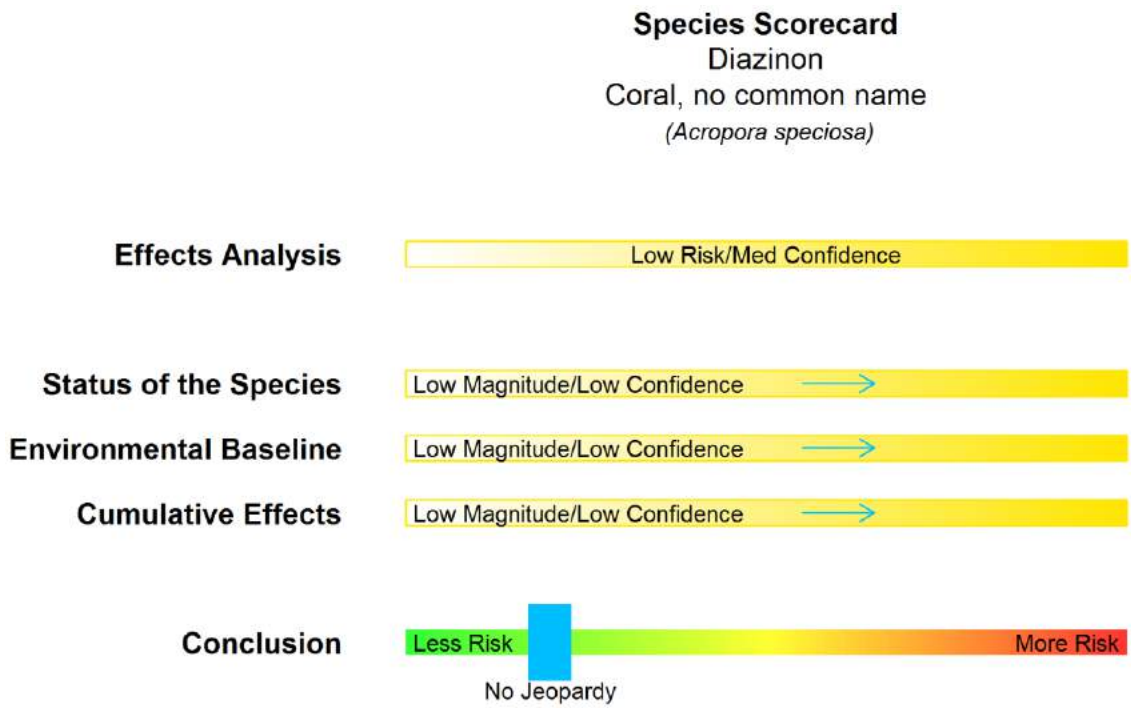

Figure 53. Species Score Card; Coral, Acropora speciosa; Diazinon

Effects Analysis: Low risk/Medium confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region; less than 5% of the population is within the action area; overall status and growth rates unknown
- Threatened
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats. About 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

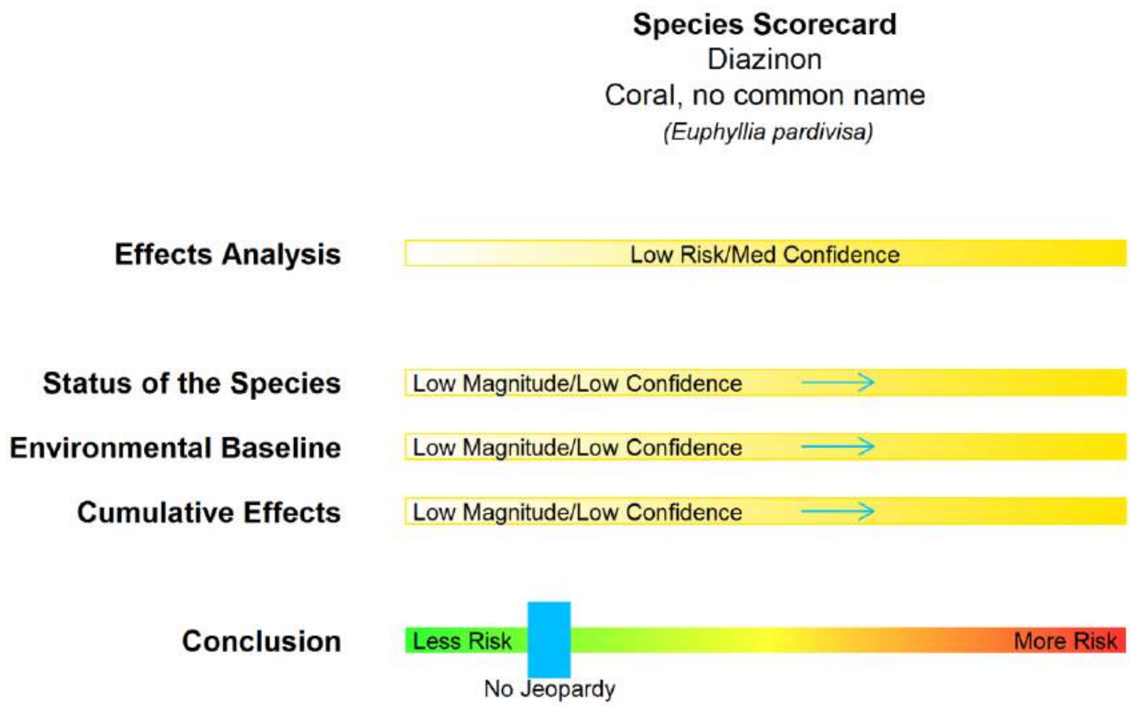

Figure 54. Species Score Card; Coral, Euphyllia pardivisa; Diazinon

Effects Analysis: Low risk/Medium confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region; less than 5% of the population is within the action area; overall status and growth rates unknown
- Threatened
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats. About 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

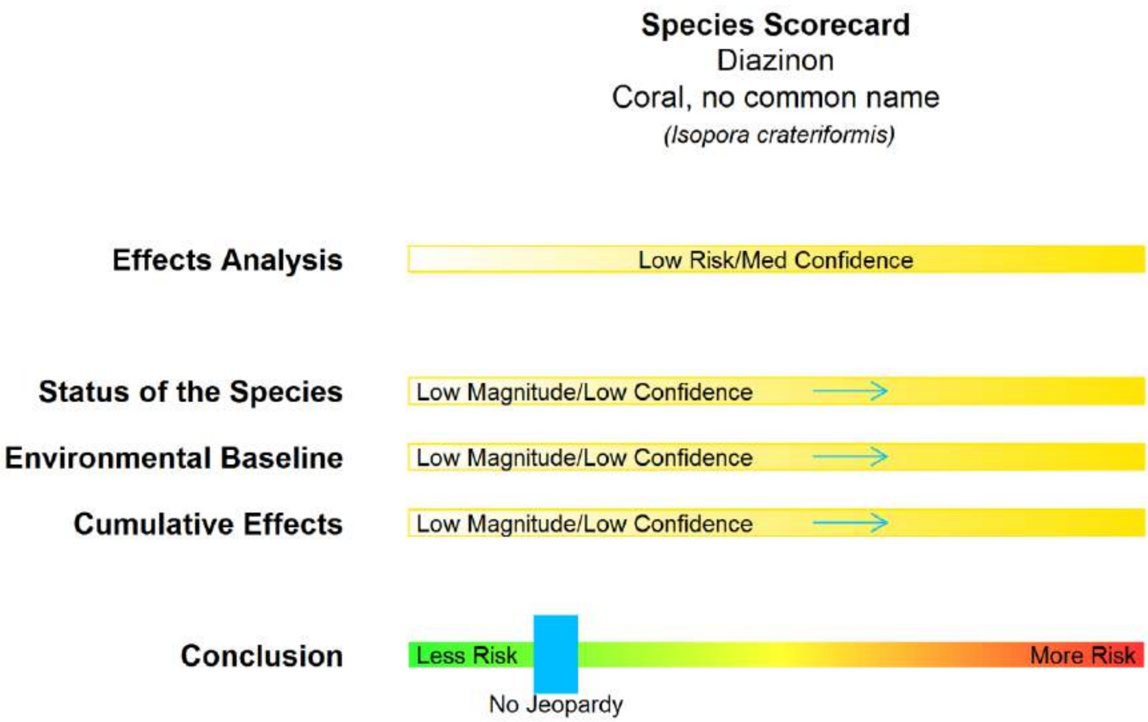

Figure 55. Species Score Card; Coral, Isopora crateriformis; Diazinon

Effects Analysis: Low risk/Medium confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region; less than 5% of the population is within the action area; overall status and growth rates unknown
- Threatened
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats. About 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

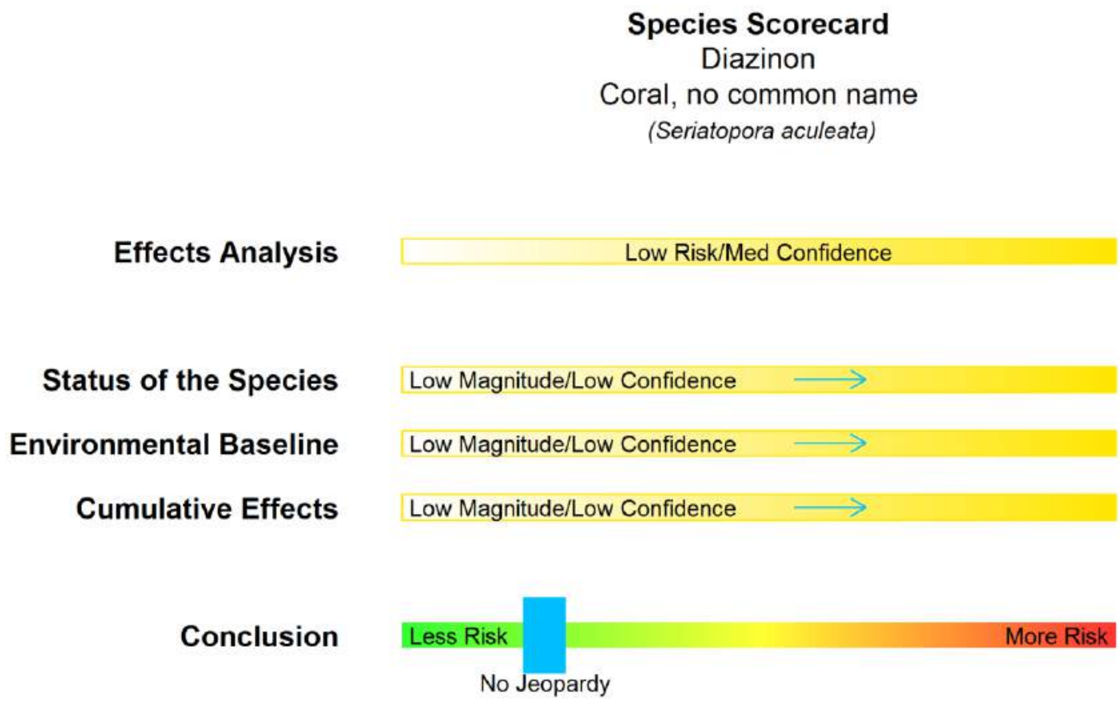

Figure 56. Species Score Card; Coral, Seriatopora aculeata; Diazinon

Effects Analysis: Low risk/Medium confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region; less than 5% of the population is within the action area; overall status and growth rates unknown
- Threatened
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats. About 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

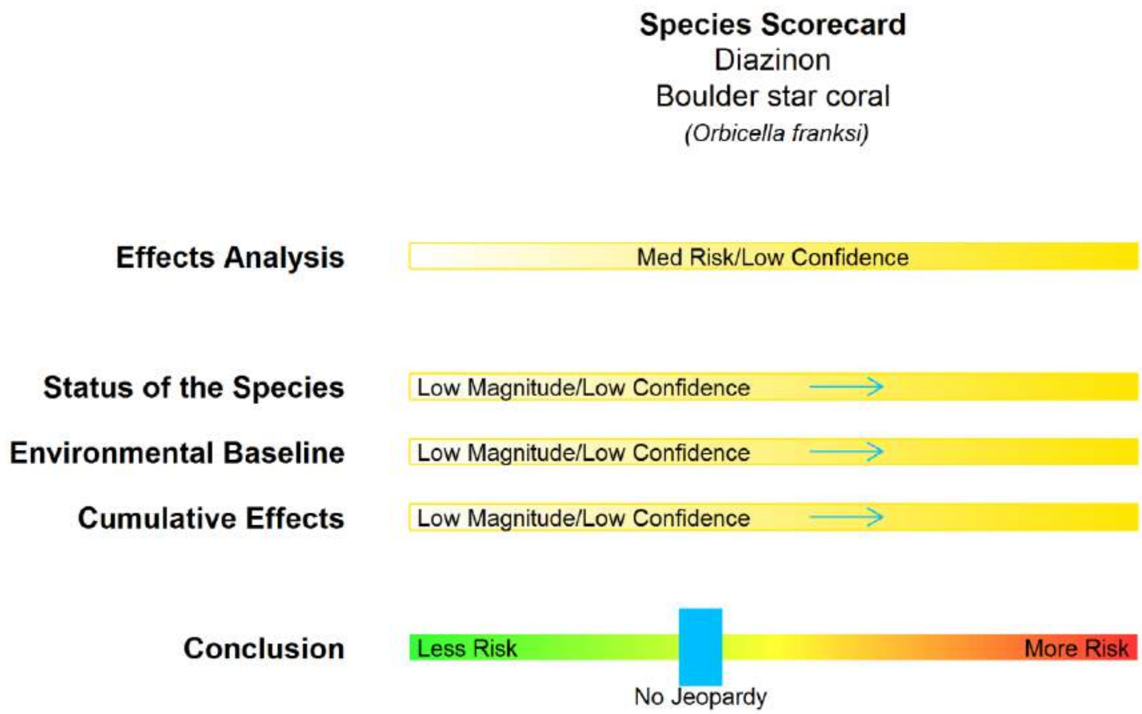

Figure 57. Species Score Card; Boulder star coral; Diazinon

Effects Analysis: Medium risk/Low confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Reductions in abundance, population is currently stable
- Threatened
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats, but most likely where colonies are proximate to river and stream mouths. A small portion of the species' range is in U.S. jurisdiction. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

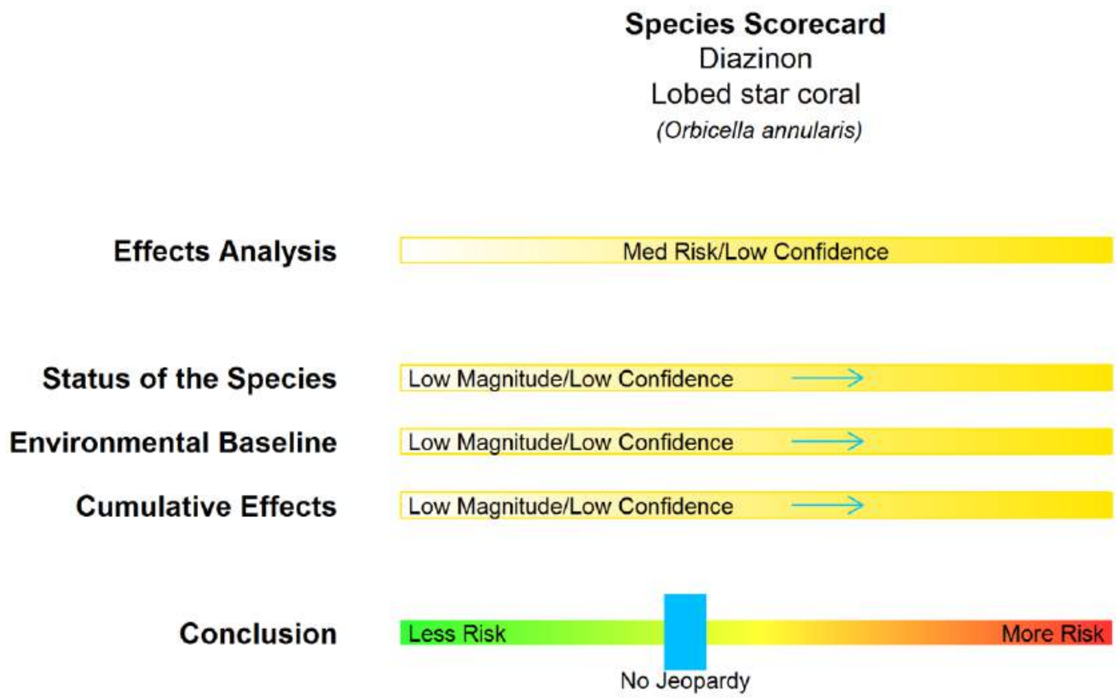

Figure 58. Species Score Card; Lobed star coral; Diazinon

Effects Analysis: Medium risk/Low confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- 60% decline 2001-2012 due to bleaching. Most were considered "partial" mortalities to the colony. Abundance is stable.
- Threatened
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats, but most likely where colonies are proximate to river and stream mouths. A small portion of the species' range is in U.S. jurisdiction. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

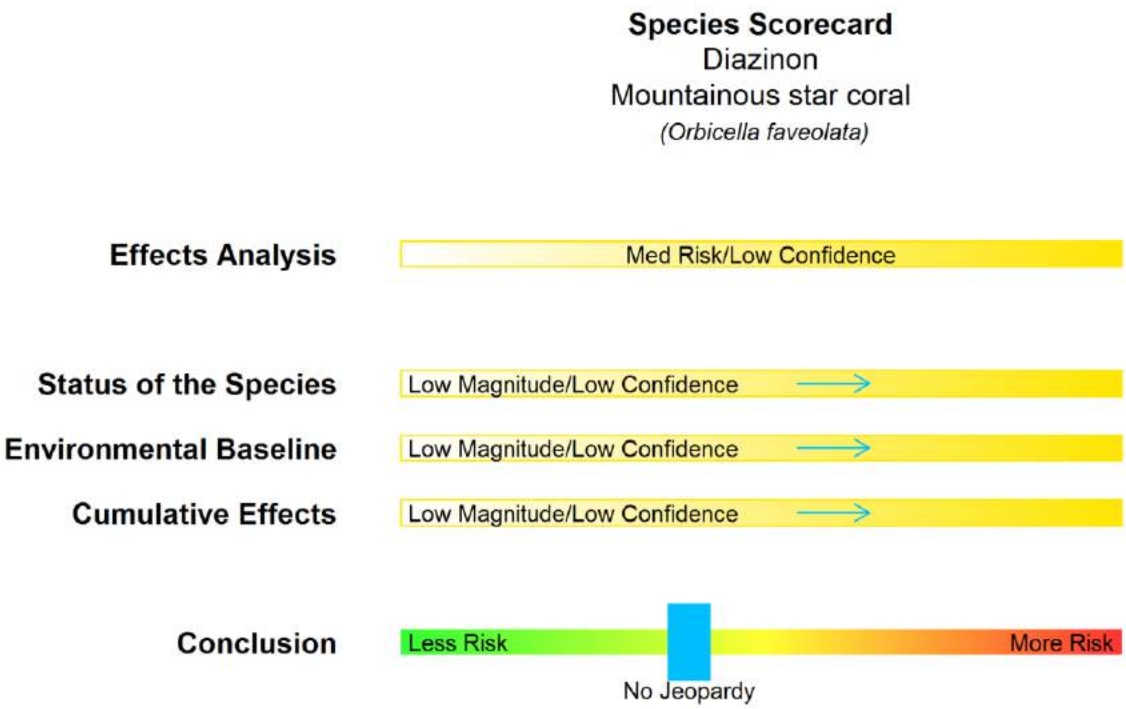

Figure 59. Species Score Card; Mountainous star coral; Diazinon

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Considered abundant; some areas have shown major declines due to warming-induced bleaching and disease
- Threatened
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats, but most likely where colonies are proximate to river and stream mouths. A small portion of the species' range is in U.S. jurisdiction. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

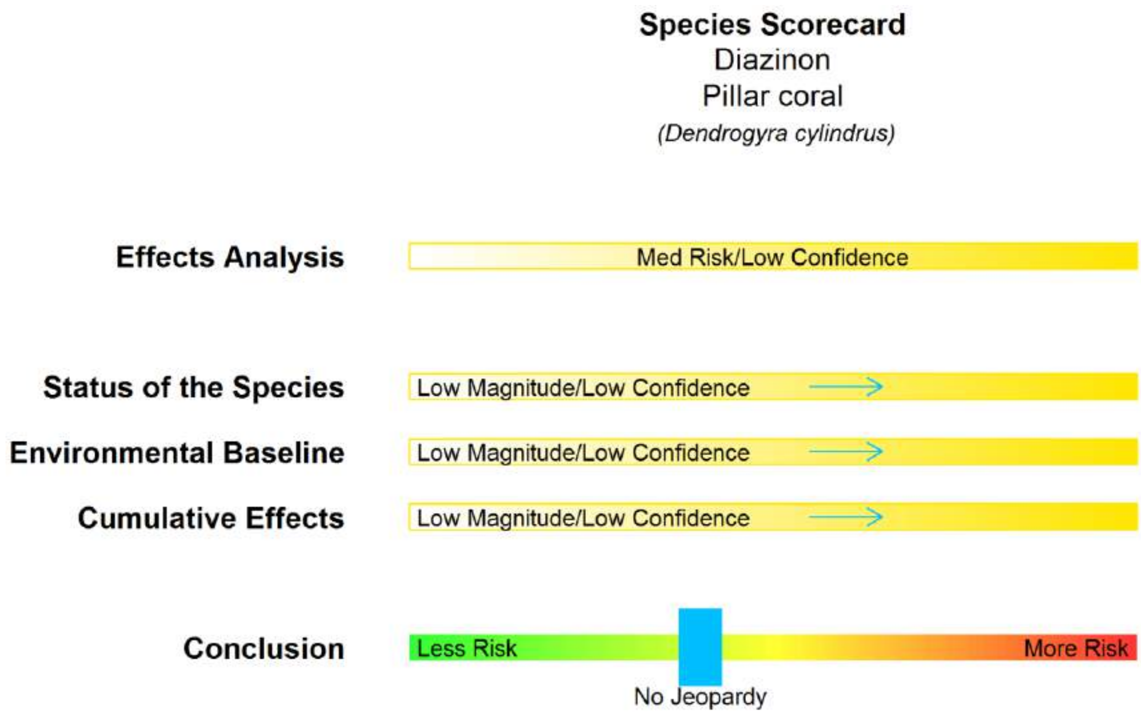

Figure 60. Species Score Card; Pillar coral; Diazinon

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Uncommon, rarely found in aggregations - yet little evidence of population declines over years of monitoring. Unknown trends in abundance or productivity
- Threatened
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats, but most likely where colonies are proximate to river and stream mouths. Only a small portion of the species' range is in U.S. jurisdiction. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

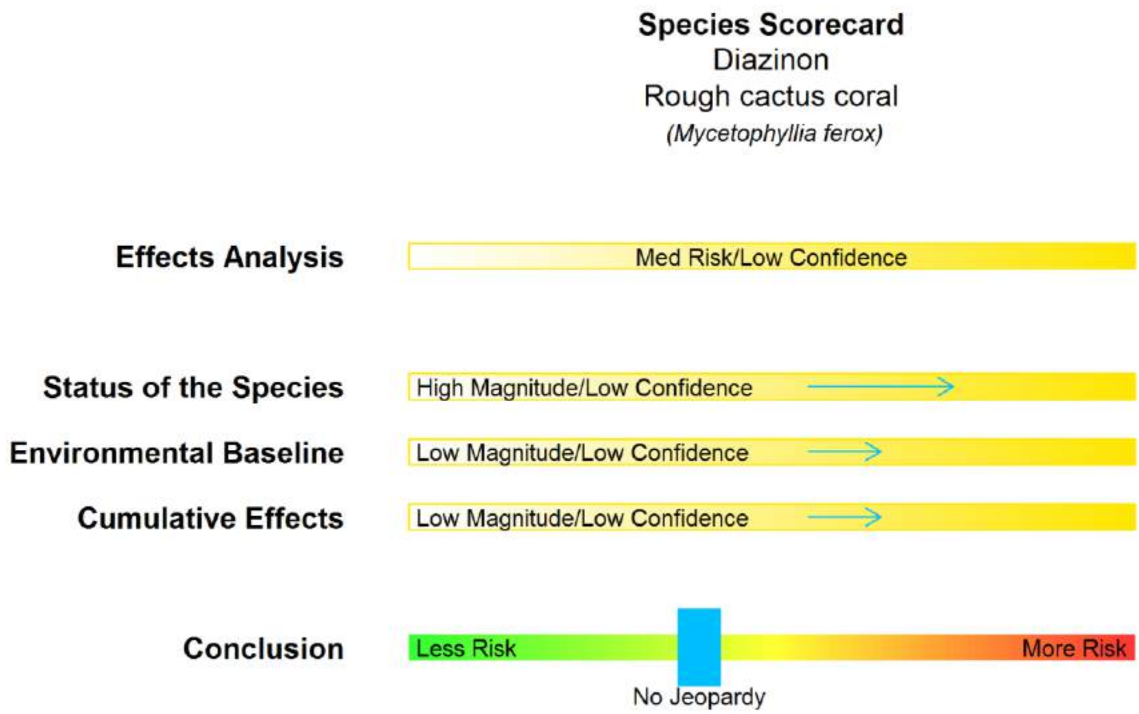

Figure 61. Species Score Card; Rough cactus coral; Diazinon

Effects Analysis: Medium risk/Low confidence

- Reduced abundance and productivity not anticipated in marine areas
- Potential effects to colonies including death and reduced settling of larvae
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Uncommon to rare. Species saw declines since the 1970's. Highly affected by disease. Unknown trends in abundance or productivity
- Threatened
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentrations in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. Exposure is uncertain in marine habitats, but most likely where colonies are proximate to river and stream mouths. Only a small portion of the species' range is in U.S. jurisdiction. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

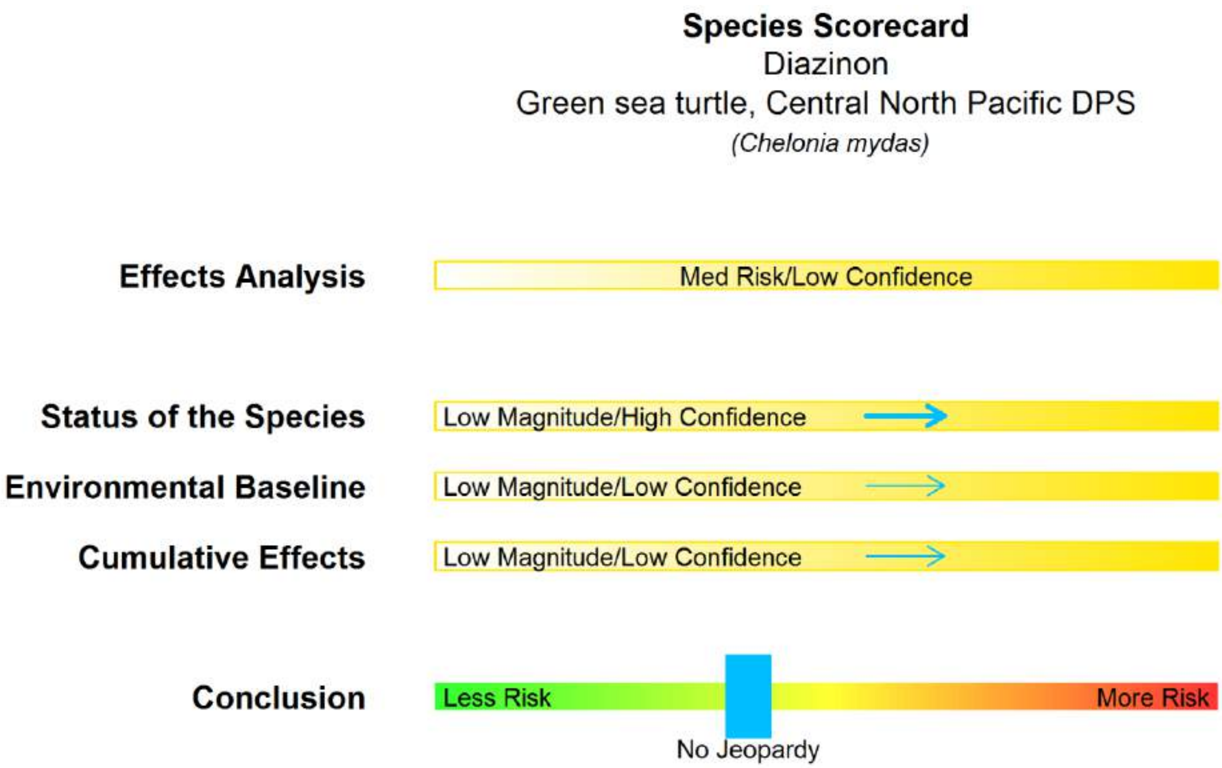

Figure 62. Species Score Card; Green sea turtle, Central North Pacific DPS; Diazinon

<u>Effects Analysis: Medium risk/Low confidence</u>

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence</u>

- Population nesting abundance is increasing at estimated rate of 4.8% annually. DPS has low level of genetic diversity. Population considered resilient.
- Threatened
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

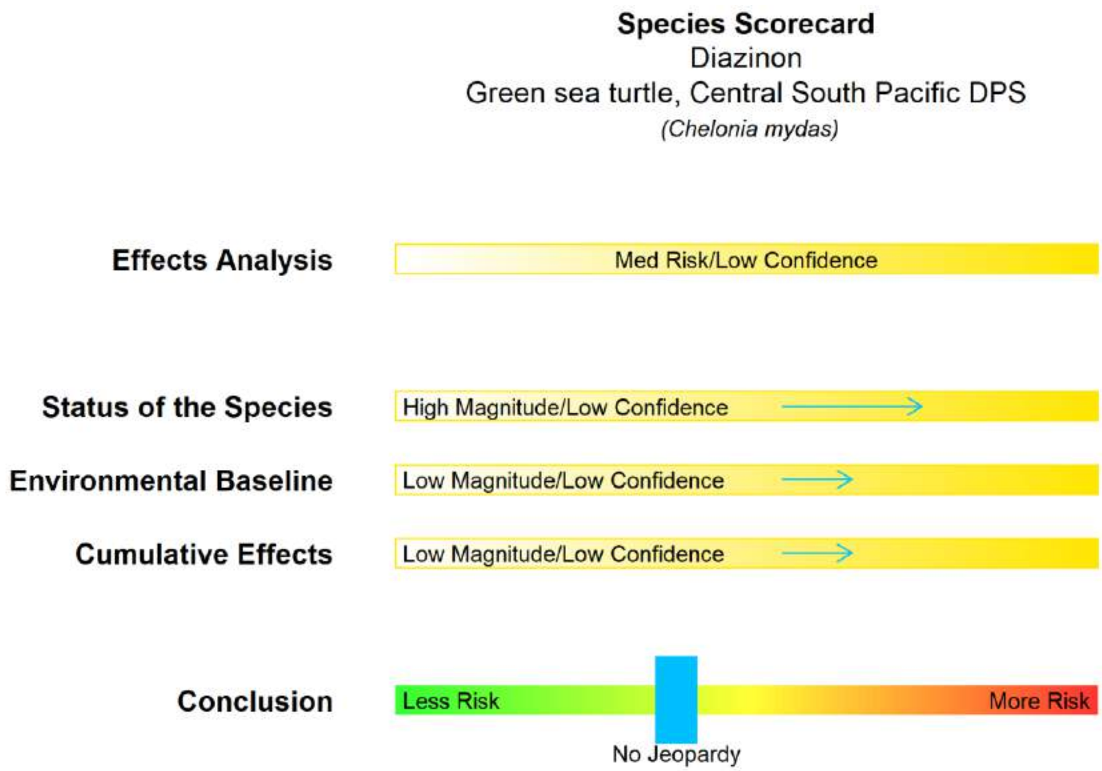

Figure 63. Species Score Card; Green sea turtle, Central South Pacific DPS; Diazinon

<u>Effects Analysis: Medium risk/Low confidence</u>

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Nesting abundance considered low, 59 known sites, most outside action area; Unknown population trends; Existing data suggest steep declines due to illegal harvest of eggs
- Endangered
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

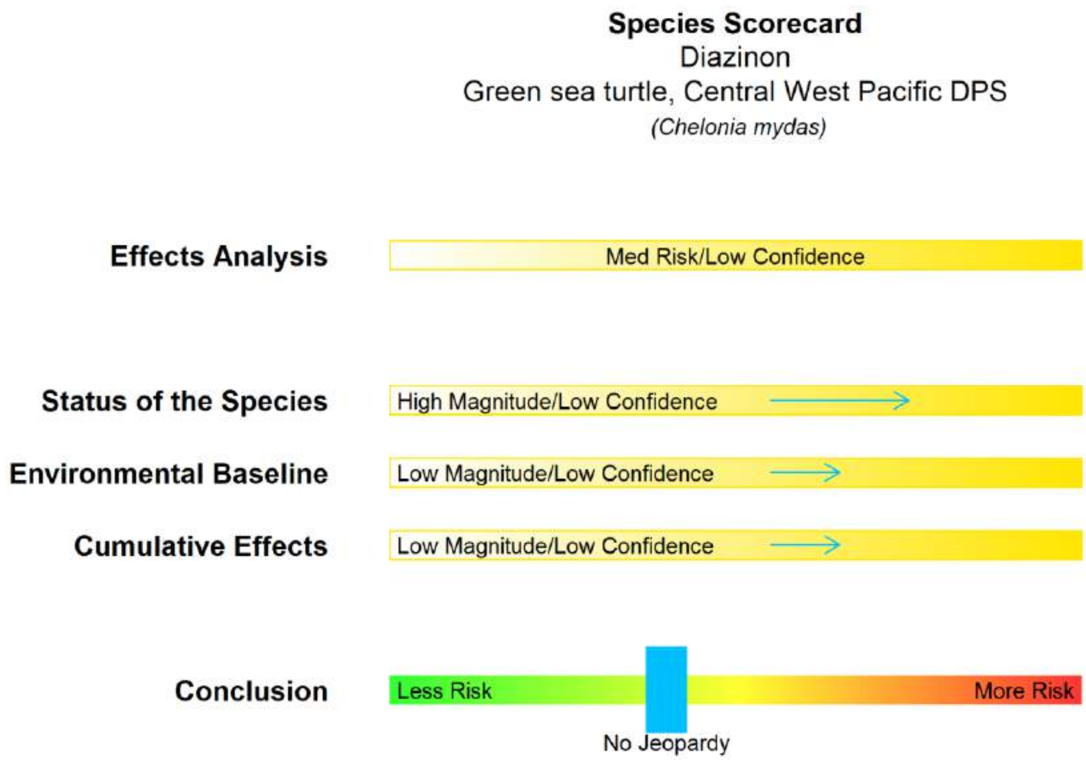

Figure 64. Species Score Card; Green sea turtle, Central West Pacific DPS; Diazinon

<u>Effects Analysis: Medium risk/Low confidence</u>

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Minimal increased risk of jeopardy; High magnitude/ Low confidence</u>

- No available population trend data; Most of species' range outside of action area.
- Endangered
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

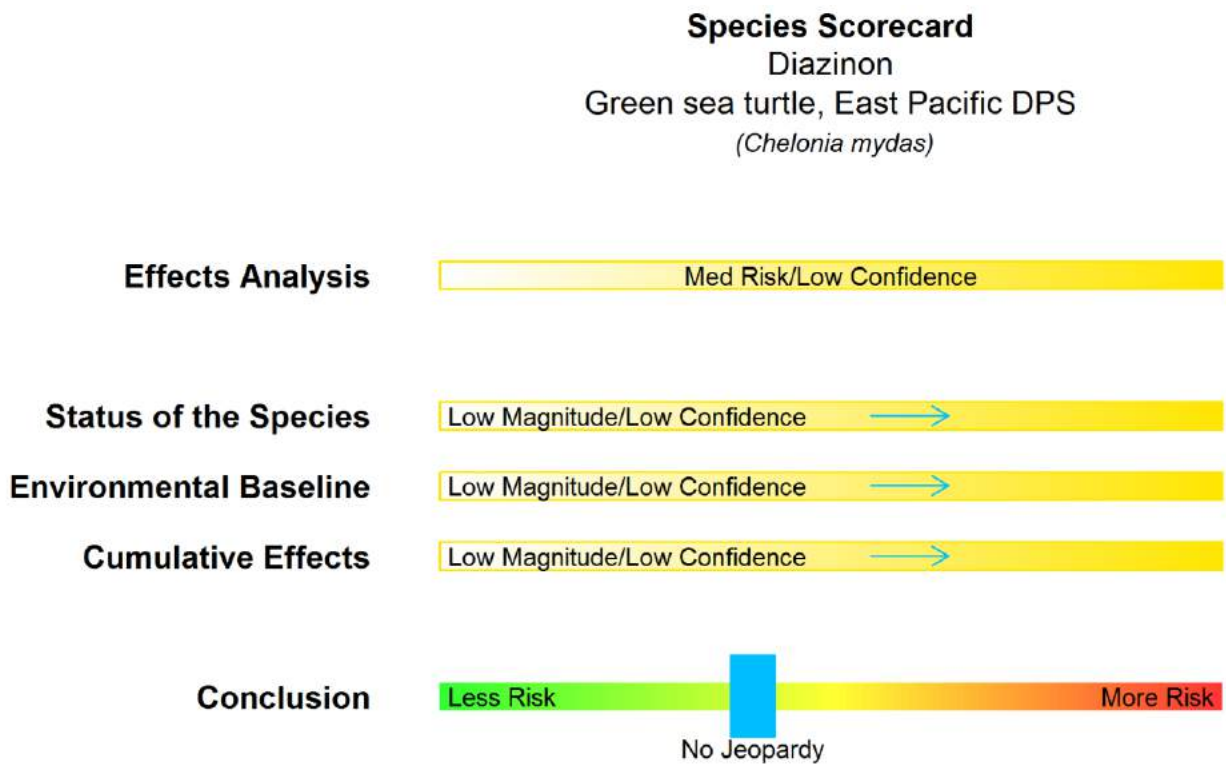

Figure 65. Species Score Card; Green sea turtle, East Pacific DPS; Diazinon

Effects Analysis: Medium risk/Low confidence

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- 39 nesting sites with an estimated 20,062 nesting females (58% of those at the largest nesting site in Colola, Mexico). Monitoring data suggest the population is increasing.
- Threatened
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of medium risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

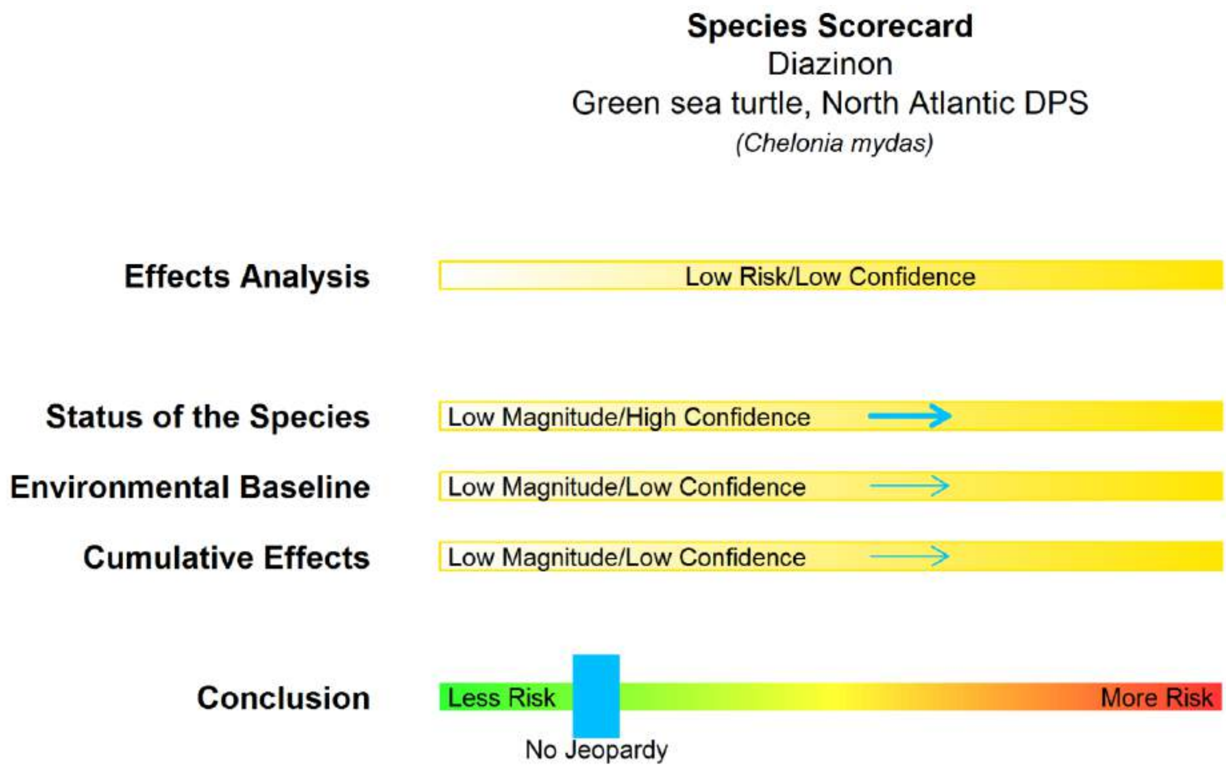

Figure 66. Species Score Card; Green sea turtle, North Atlantic DPS; Diazinon

<u>Effects Analysis: Low risk/Low confidence</u>

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Population shows increasing trend
- Threatened
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

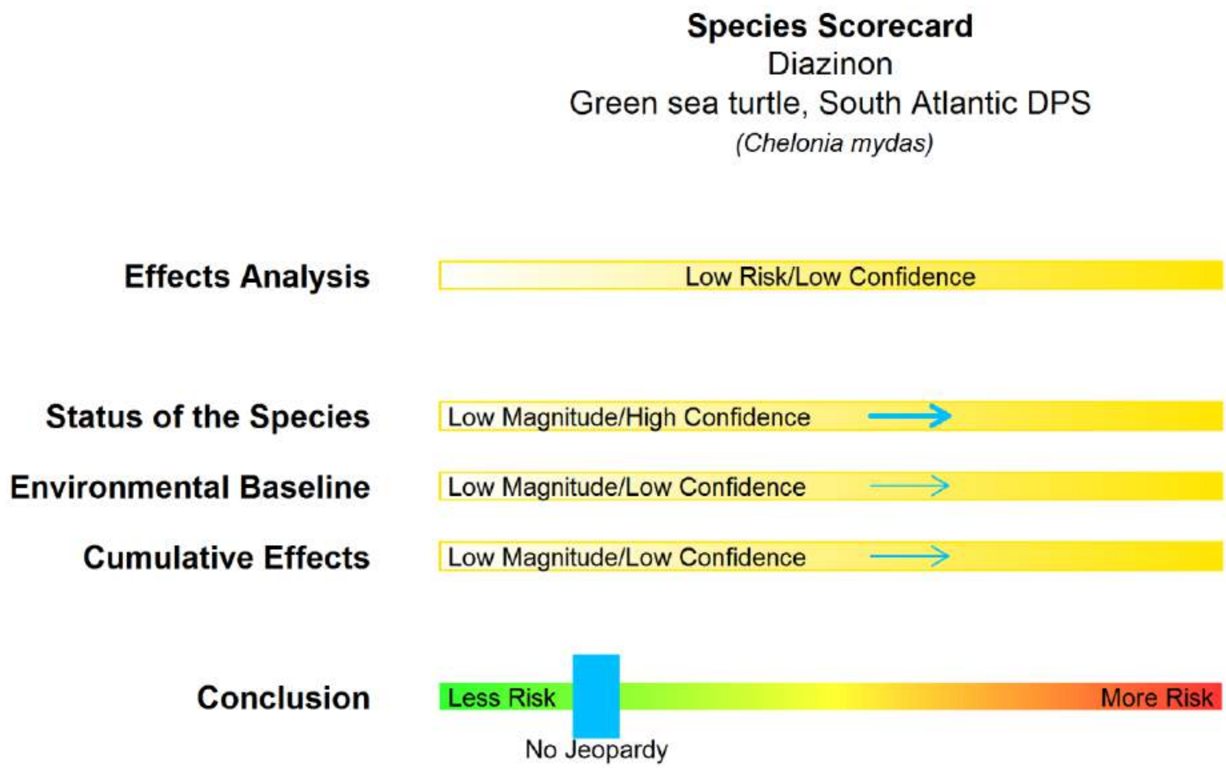

Figure 67. Species Score Card; Green sea turtle, South Atlantic DPS; Diazinon

Effects Analysis: Low risk/Low confidence

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Sparse data available, suggests population is increasing; Most of DPS range outside of the action area
- Threatened
- Recovery criteria not all met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

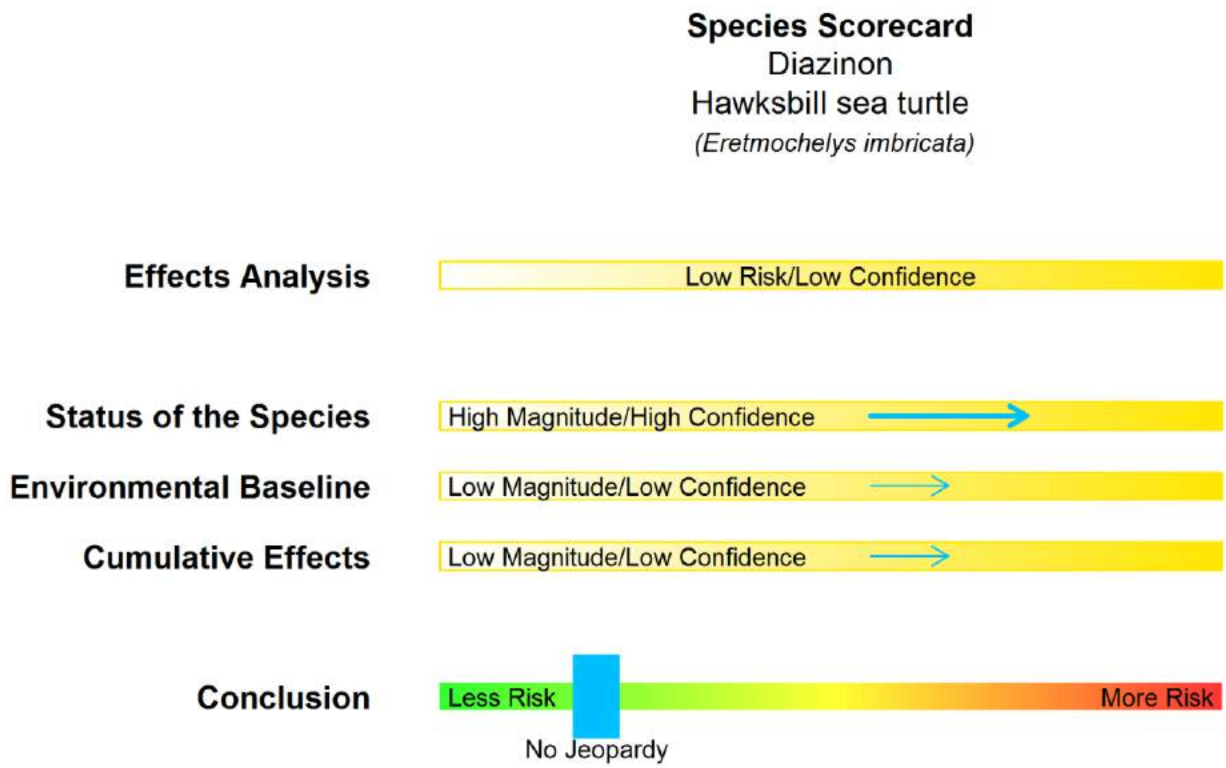

Figure 68. Species Score Card; Hawksbill sea turtle; Diazinon

<u>Effects Analysis: Low risk/Low confidence</u>

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Population abundance improving in Atlantic and Indian Ocean; abundance declining in Pacific Ocean over the last 20 - 100 years. 68% of nesting sites exhibited declines.
- Endangered
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>**Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy**</u>

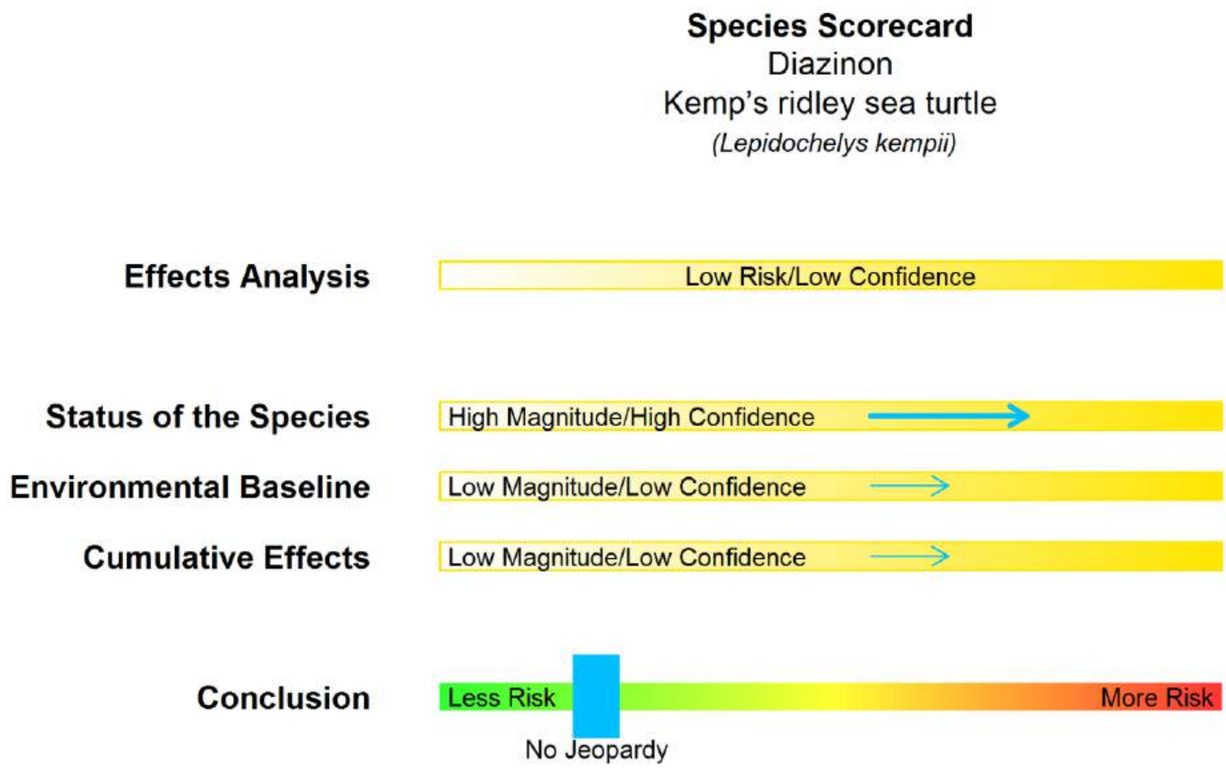

Figure 69. Species Score Card; Kemp's ridley sea turtle; Diazinon

<u>Effects Analysis: Low risk/Low confidence</u>

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Minimal increased risk of jeopardy; High magnitude/ High confidence</u>

- Abundance trends negative
- Endangered
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> We find low confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>**Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy**</u>

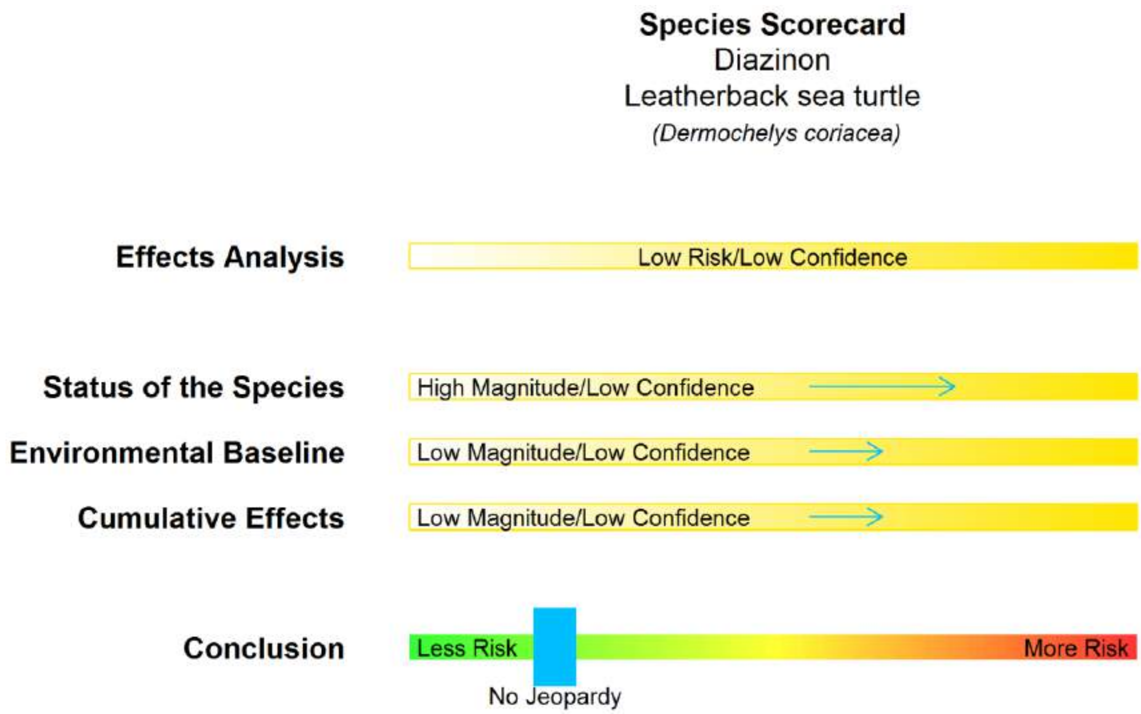

Figure 70. Species Score Card; Leatherback sea turtle; Diazinon

Effects Analysis: Low risk/Low confidence

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; High magnitude/ Low confidence

- Pacific population declined from 81,000 in to less than 3,000 with a continued rate of loss of approximately 6%. Atlantic population is stable and showing signs of increasing growth of between 4-5.6% in Florida and 9-13% in the U.S. Virgin Islands.
- Endangered
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: We find low confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

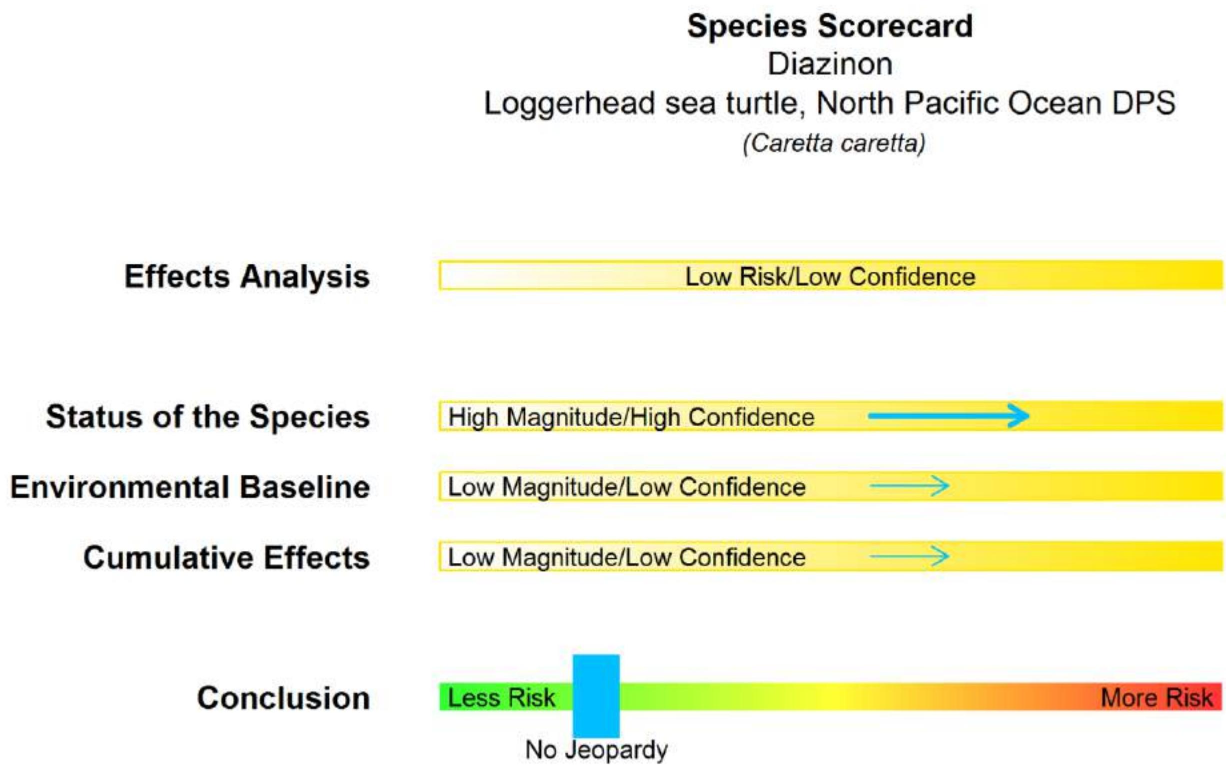

Figure 71. Species Score Card; Loggerhead sea turtle, North Pacific Ocean DPS; Diazinon

Effects Analysis: Low risk/Low confidence

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; High magnitude/ High confidence

- Population growth rate estimated at 0.032; depressed compared to historical numbers.
- Threatened; Population has declined an estimated 80% in past 20 years.
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: We find low confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

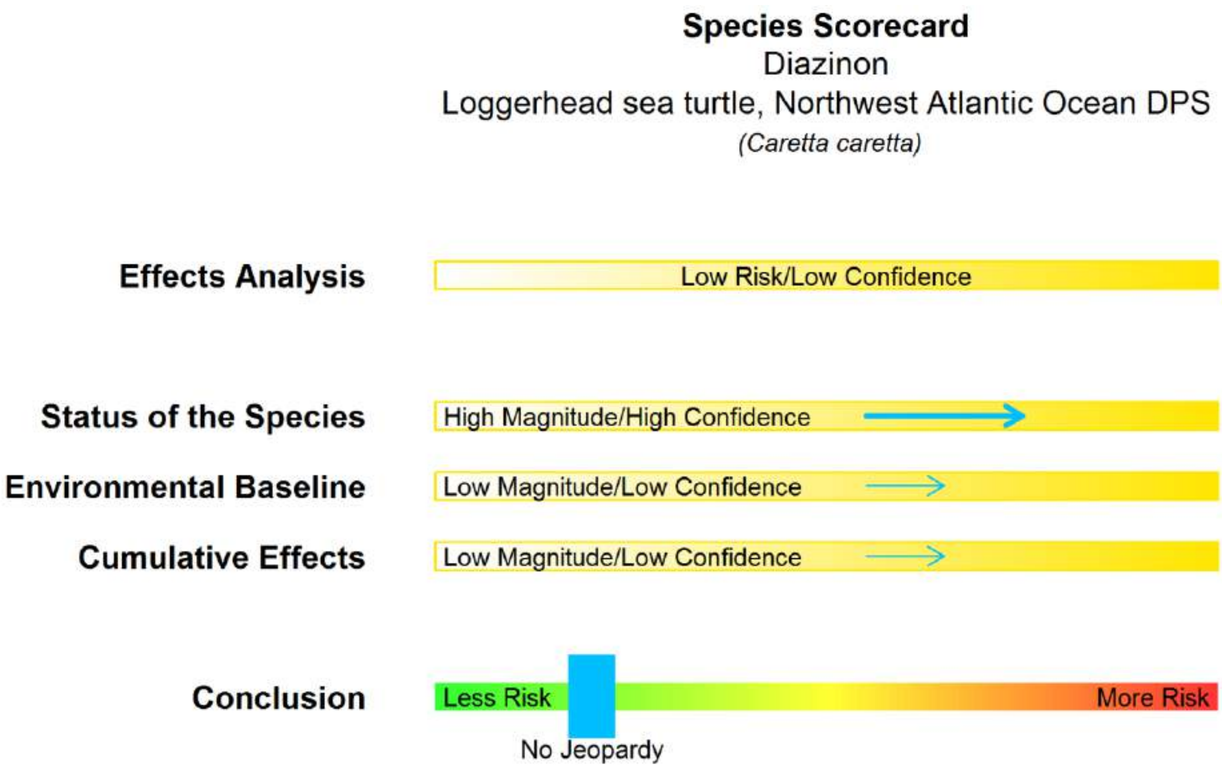

Figure 72. Species Score Card; Loggerhead sea turtle, Northwest Atlantic Ocean DPS; Diazinon

Effects Analysis: Low risk/Low confidence

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- All sub-populations exhibiting negative population growth rates
- Threatened
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: We find low confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

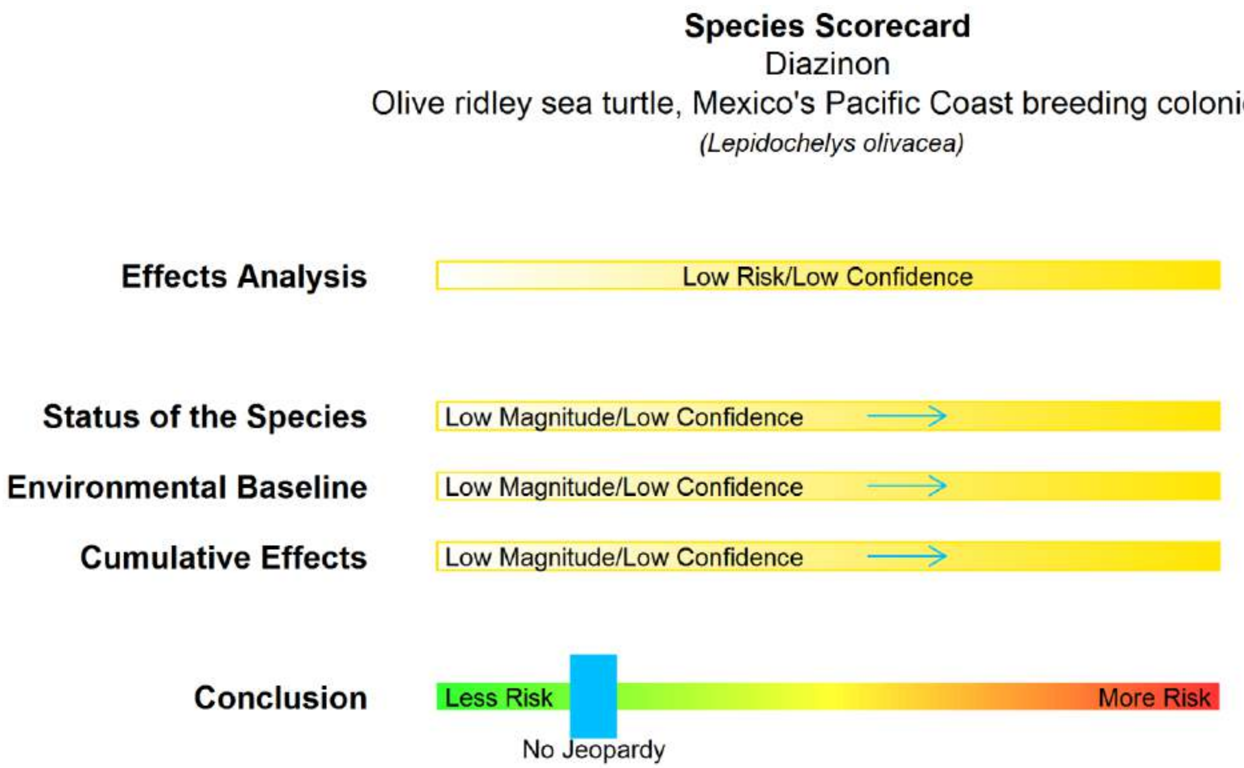

Figure 73. Species Score Card; Olive ridley sea turtle, Mexico's Pacific Coast breeding colonies; Diazinon

Effects Analysis: Low risk/Low confidence

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

Status of the Species: Increased risk of jeopardy; Low magnitude/ Low confidence

- 50% decline in a population abundance since the 1960's; 80% reductions in some nesting populations in the Western Atlantic Ocean since 1967;
- Threatened;
- Recovery criteria not met;

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: We find low confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

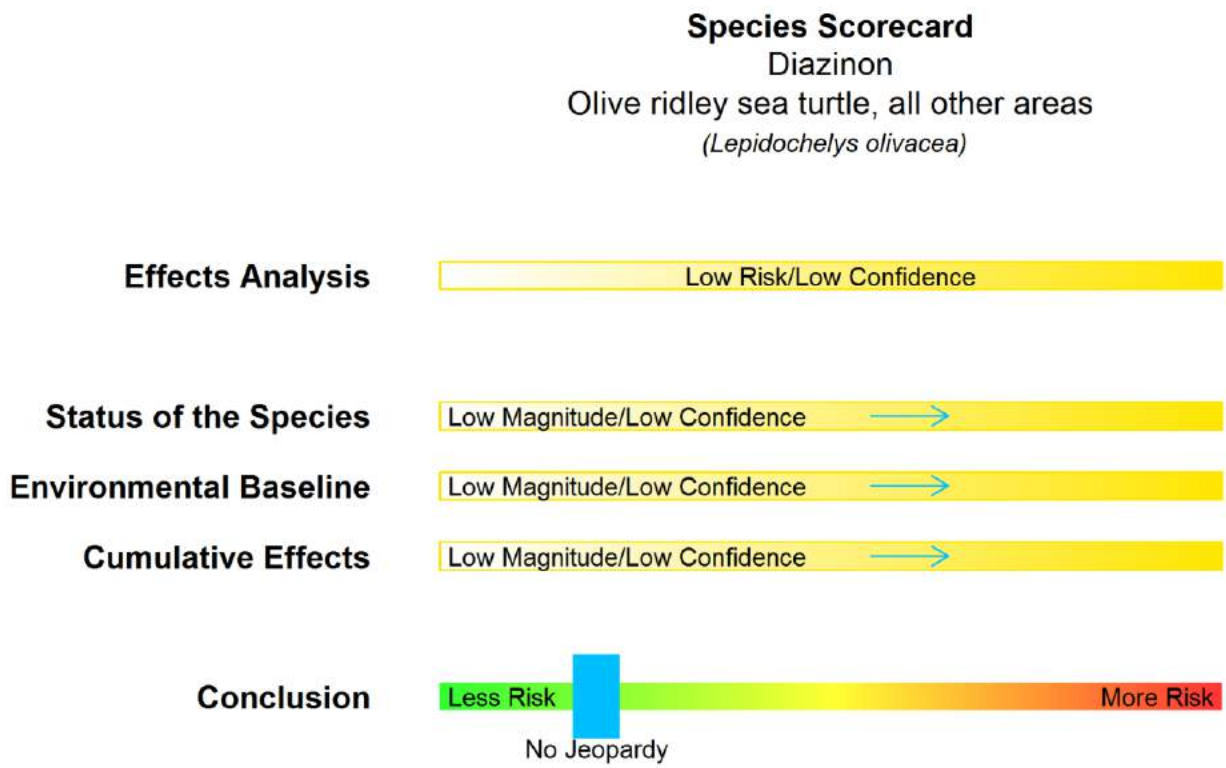

Figure 74. Species Score Card; Olive ridley sea turtle, all other areas; Diazinon

Effects Analysis: Low risk/Low confidence

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity and impaired swimming
- Uncertain exposure concentrations in marine habitats

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Some nesting populations are stable or increasing, but most remain severely depressed. Most populations are outside of the action area.
- Threatened
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: We find low confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk while in shallow coastal areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

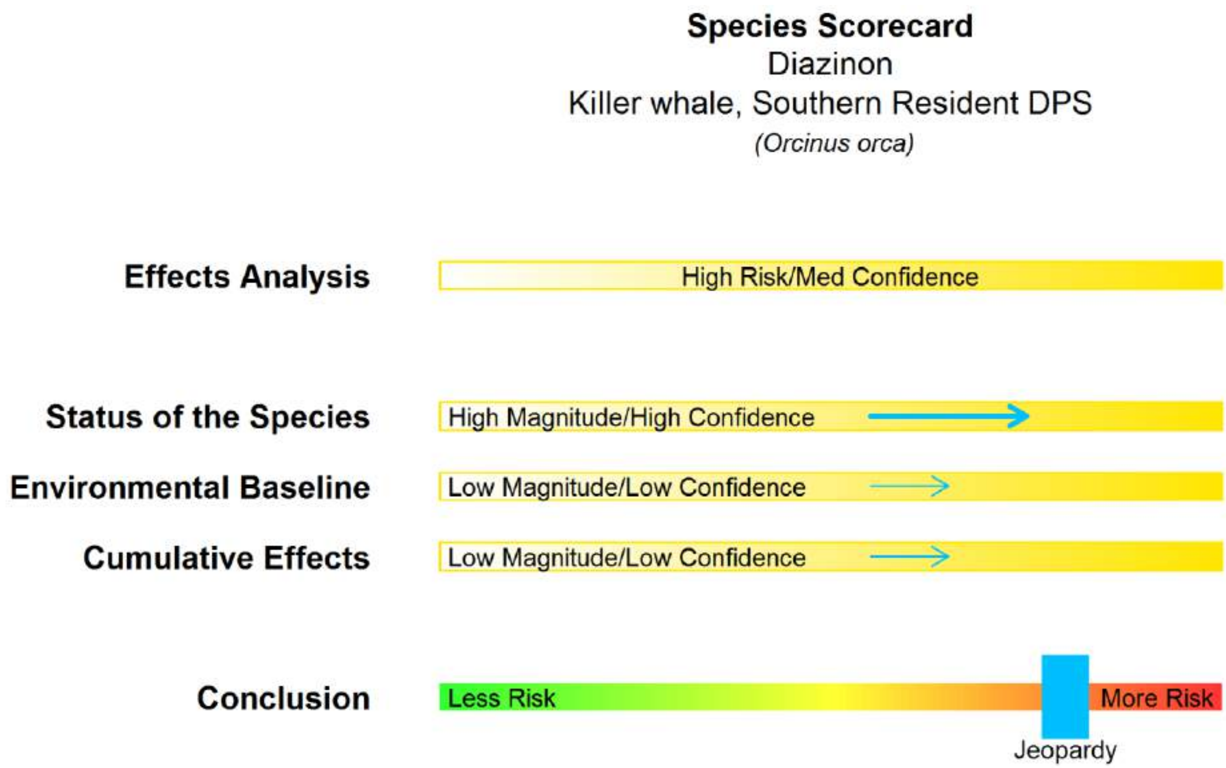

Figure 75. Species Score Card; Killer whale, Southern Resident DPS; Diazinon

<u>Effects Analysis: High risk/Medium confidence</u>

- Reduced abundance anticipated based on effects to prey (Chinook salmon)
- Anticipated effects include reduced availability of Chinook salmon and other fish prey leading to reduced growth, chronic lack of food;

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Stable to declining populations in past decade, unstable population structure
- Endangered, very small population size (n=76 individuals)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/Low confidence</u>

- Elevated temperatures may occur in marine habitats;
- Environmental mixtures anticipated in marine habitats with high uncertainty of toxicity

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures may occur in marine waters

<u>Conclusion:</u> We find medium confidence of a high risk to Southern Resident Killer whales based on expected adverse effects to orca whales' prey base. We have high confidence in exposure concentrations predicted for freshwater habitats where the Orca's prey is most at risk during spawning, rearing, and migration. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action due to continuous reductions in prey.

<u>Diazinon is likely to jeopardize the continued existence of this species: Jeopardy</u>

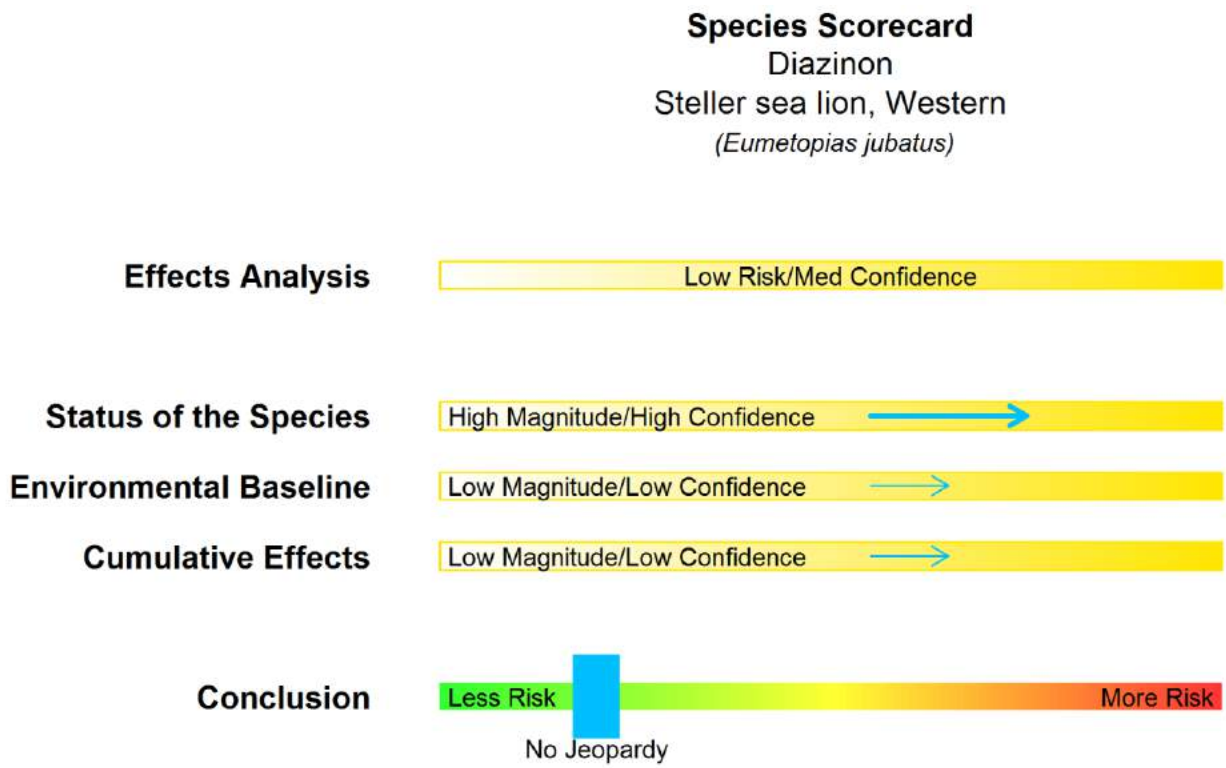

Figure 76. Species Score Card; Steller sea lion, Western; Diazinon

Effects Analysis: Low risk/Medium confidence

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity, impaired swimming, and reduced prey abundance
- Uncertain exposure concentrations in marine habitats

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- 30% of 1950's historical abundance, stable to slight negative population trend
- Endangered
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect sea lions
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: We find medium confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk from reductions in prey. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

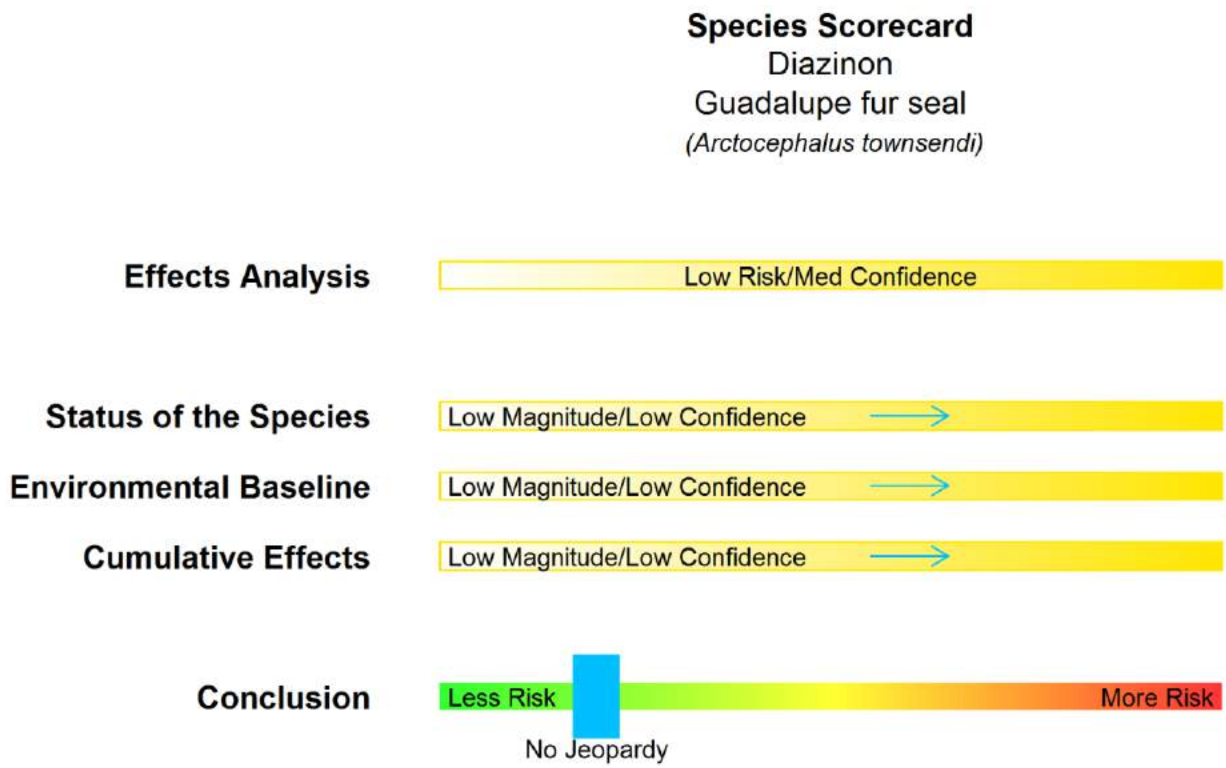

Figure 77. Species Score Card; Guadalupe fur seal; Diazinon

<u>Effects Analysis: Low risk/Medium confidence</u>

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity, impaired swimming, and reduced prey abundance
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- 5% of historical abundance, increasing abundance trend;
- Threatened;
- No recovery criteria established;

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters not anticipated to affect sea lions
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters but effects uncertain

<u>Conclusion:</u> We find medium confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk from reductions in prey. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

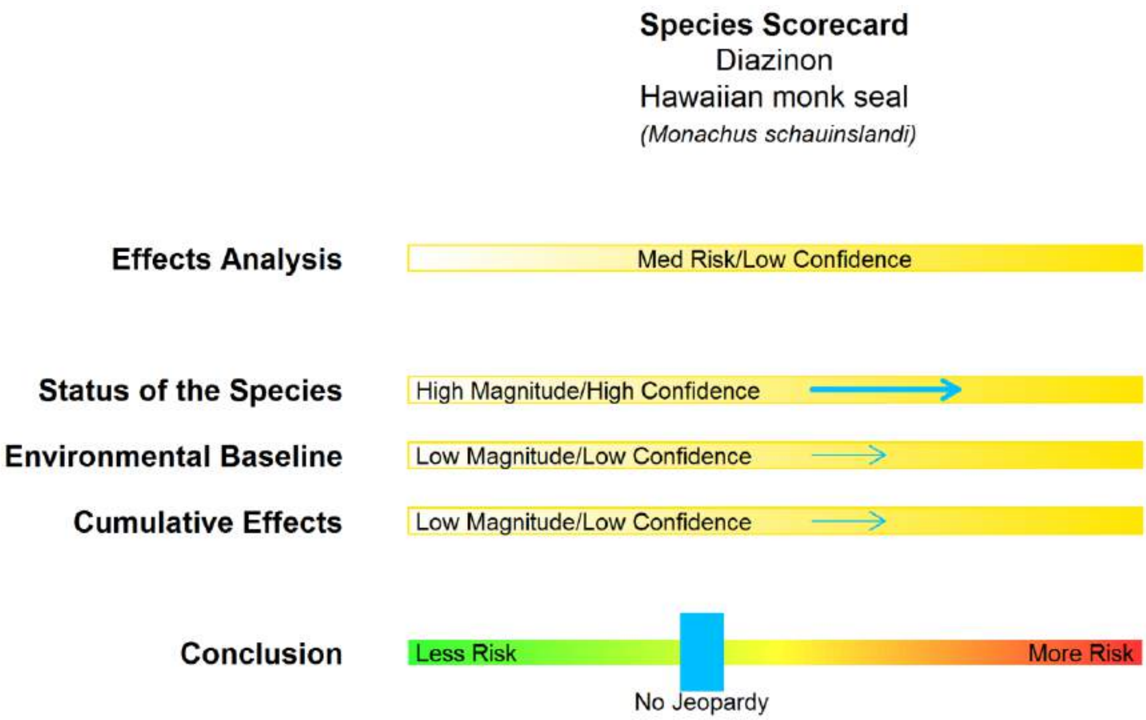

Figure 78. Species Score Card; Hawaiian monk seal; Diazinon

<u>Effects Analysis: Medium risk/Low confidence</u>

- Significant reductions in abundance and productivity not anticipated in marine areas
- Potential effects include reduced cholinesterase activity, impaired swimming, and reduced prey abundance
- Uncertain exposure concentrations in marine habitats

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Less than 40% of 1958 abundance, two populations have increasing trends, six populations have declining trends; very low genetic diversity
- Endangered
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters not anticipated to affect sea lions
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters but effects uncertain

<u>Conclusion:</u> We find medium confidence of low risk to the species based on predicted marine exposure concentrations and expected population-level effects. The species is most at risk from reductions in prey. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

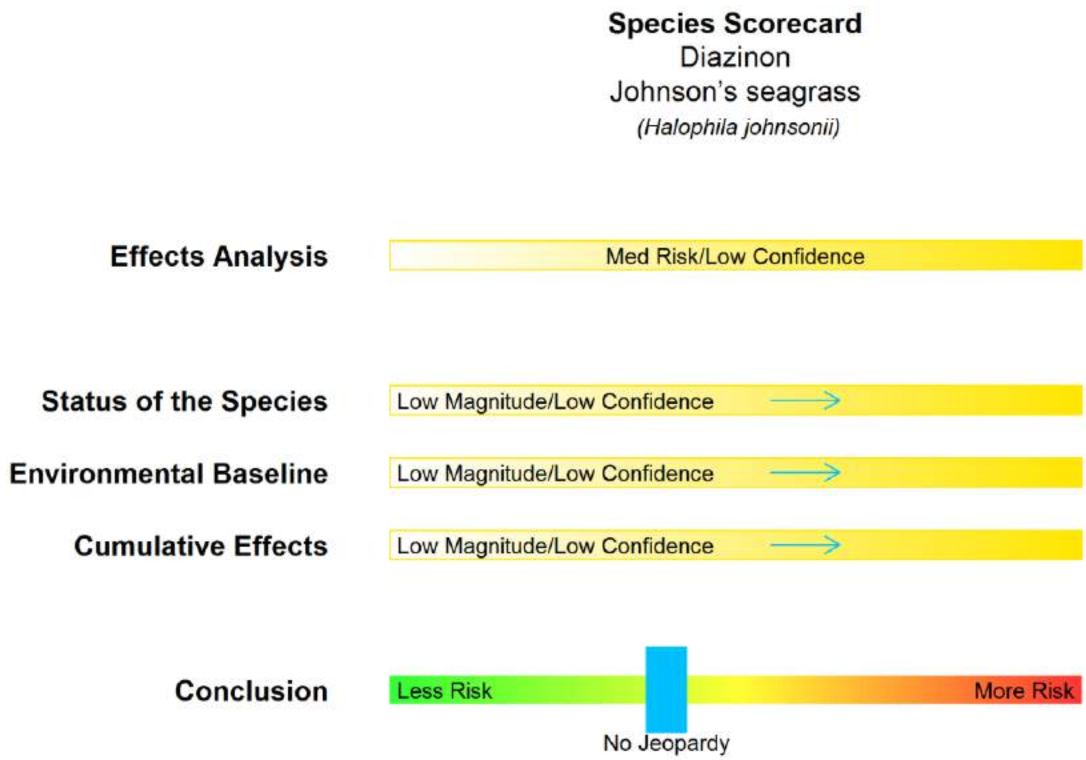

Figure 79. Species Score Card; Johnson's seagrass; Diazinon

Effects Analysis: Medium risk/Low confidence
- Reduced abundance not anticipated
- Potential effects include phytotoxicity

Status of the Species: Increased risk of jeopardy; Low magnitude/ Low confidence
- No trend data on abundance
- Threatened;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence
- Elevated temperatures in marine waters not anticipated to affect seagrass
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence
- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a high likelihood of exposure and a low likelihood of effects to the species based on low confidence in exposure concentrations and low toxicity. The species is most at risk from direct toxicity. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Diazinon is not likely to jeopardize the continued existence of this species: No Jeopardy

CHAPTER 21

INTEGRATION AND SYNTHESIS FOR LISTED SPECIES

MALATHION

TABLE OF CONTENTS

21 MALATHION

21.1 Introduction

The integration and synthesis section is the final step in our assessment of the risk posed to species and critical habitat as a result of implementing the proposed action. In this section, we add the effects of the action (Chapter 14) to the environmental baseline (Chapter 10) and the cumulative effects (Chapter 18) to formulate the agency's biological opinion as to whether the proposed action is likely to: (1) reduce appreciably the likelihood of both the survival and recovery of an Endangered Species Act (ESA)-listed species in the wild by reducing its numbers, reproduction, or distribution; or (2) appreciably diminish the value of designated critical habitat for the conservation of an ESA-listed species. These assessments are made in full consideration of the status of the species (Chapter 9).

We treat the information from the status of the species, environmental baseline, and cumulative effects, as "risk modifiers," in that the effects described in the effects analysis section may be modified by the condition of the species; the condition of environmental baseline, and the anticipated cumulative effects. The key questions addressed include:

1) Status of the Species:
    - Are abundance, spatial distribution, and productivity trends increasing, decreasing or stable?
    - Is the species listed as threatened, or as endangered?
    - Have recovery goals been met, or are they on a sustained positive trajectory toward recovery?
2) Environmental Baseline:
    - Are freshwater temperatures elevated?
    - Are pesticide mixtures present, or anticipated based on current land use?
3) Cumulative Effects:
    - Will future temperatures impair species aquatic habitats?
    - Will future hydrologic flows impair freshwater species habitats?

Once each of the above sections is evaluated i.e., questions answered, the effects of the action and the risk modifiers are depicted graphically on a "scorecard." First, we assign a magnitude of influence (low or high) indicated graphically with one of two lengths of arrows. The shorter of the two arrows indicates a low magnitude, while the longer of the two arrows indicates a high magnitude as a risk modifier. The direction an arrow is pointed indicates the directionality of the risk modifier. For example, an environmental baseline arrow pointing towards more risk may indicate that environmental mixtures and elevated temperatures occur in the Environmental Baseline, which further stresses the species in question. We also assign a level of confidence in our selection of the small and large magnitude, indicated by a bold arrow (high confidence) or an un-bolded arrow (low confidence). The final arrow representing the influence on risk is graphically depicted on each species' scorecard.

Figure 1. Example of arrows to represent direction, magnitude, and confidence of risk modifiers

Conclusion Section:

With full consideration of the status of the species and the designated critical habitat, we construct a description of the effects of the action within the action area on populations or subpopulations, when added to the environmental baseline and the cumulative effects, to determine whether the action could reasonably be expected to:

- Reduce appreciably the likelihood of survival and recovery of ESA-listed species in the wild by reducing its numbers, reproduction, or distribution, and state our conclusion as to whether the action is likely to jeopardize the continued existence of such species; or
- Appreciably diminish the value of designated critical habitat for the conservation of an ESA-listed species, and state our conclusion as to whether the action is likely to destroy or adversely modify designated critical habitat.

A scorecard is generated for each species and designated critical habitat. The effects of the proposed action is considered, as modified by the magnitude and confidence of the three arrows. Next, a no-jeopardy or jeopardy bar is placed on the risk bar i.e., the colored bar beginning with green (less risk) to red (more risk) (***Figure 2***).

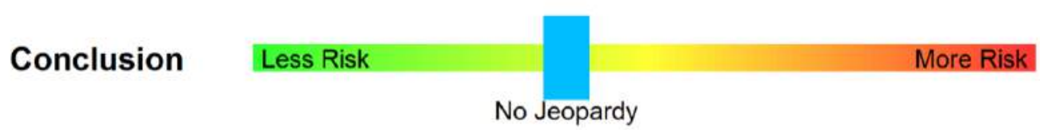

Figure 2: Example conclusion graphic

21.2 Species Scorecards

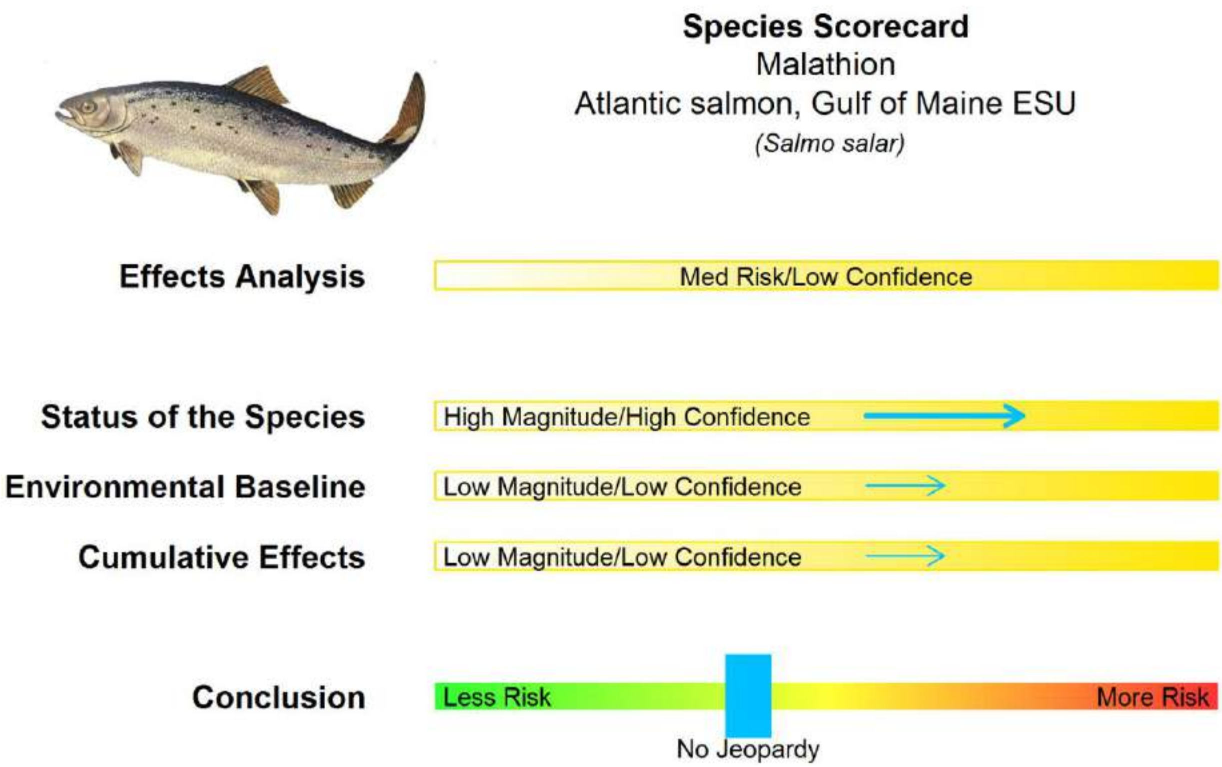

Figure 3. Species Score Card; Atlantic salmon, Gulf of Maine Evolutionarily Significant Unit (ESU); Malathion

Effects Analysis: Medium risk/Low confidence

- Salmon occupying coastal, shallow areas may experience reduced abundance.
- Anticipated effects may include death, reduced cholinesterase activity, reduced prey abundance, and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Abundance is declining, low resilience to disturbance, sustained by hatcheries
- Endangered species population estimated at 0.3% of historical levels
- Proposed action may hinder attainment of recovery goals in coastal areas

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters not anticipated to affect species
- Environmental mixtures not anticipated to substantially affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures in marine areas uncertain to affect species
- No anticipated hydrologic effects in marine waters that would affect species

Conclusion: In their marine habitats, we find a low likelihood of exposure and effects to the species as a whole based on low confidence in exposure concentrations predicted for these open water saltwater habitats. The species is most at risk while in coastal, estuarine areas where they spend a small portion of their lives. Potential reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

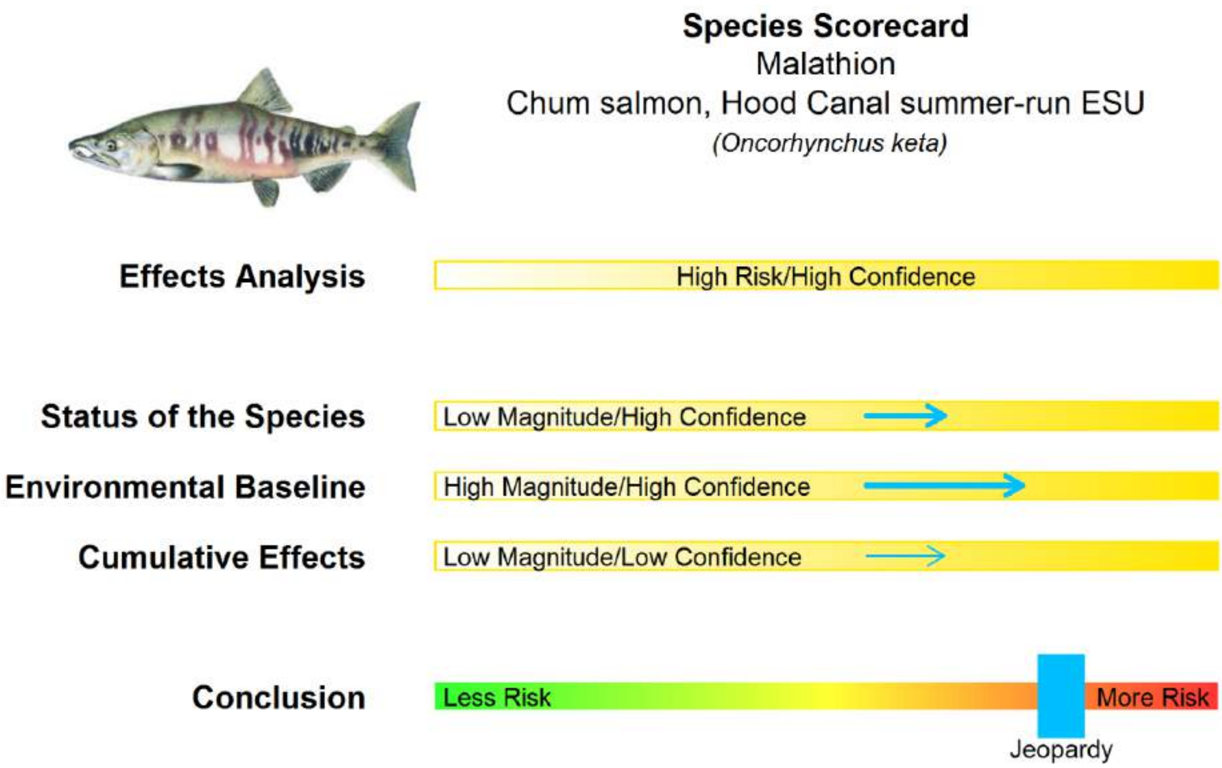

Figure 4. Species Score Card; Chum salmon, Hood Canal summer-run ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Salmon occupying freshwater and nearshore areas likely experience reduced abundance and productivity.
- Anticipated effects include death, reduced cholinesterase activity, reduced prey abundance, impaired swimming, and reduced productivity.

<u>Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence</u>

- Stable to increasing abundance trend, increasing population productivity
- Threatened species; 6 of 15 populations extirpated or nearly extirpated
- Proposed action may hinder attainment of some recovery goals

<u>Environmental Baseline: Minimal increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures anticipated in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures likely
- Anticipated hydrologic effects in freshwater areas may affect species

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species as a whole based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in freshwater and nearshore areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

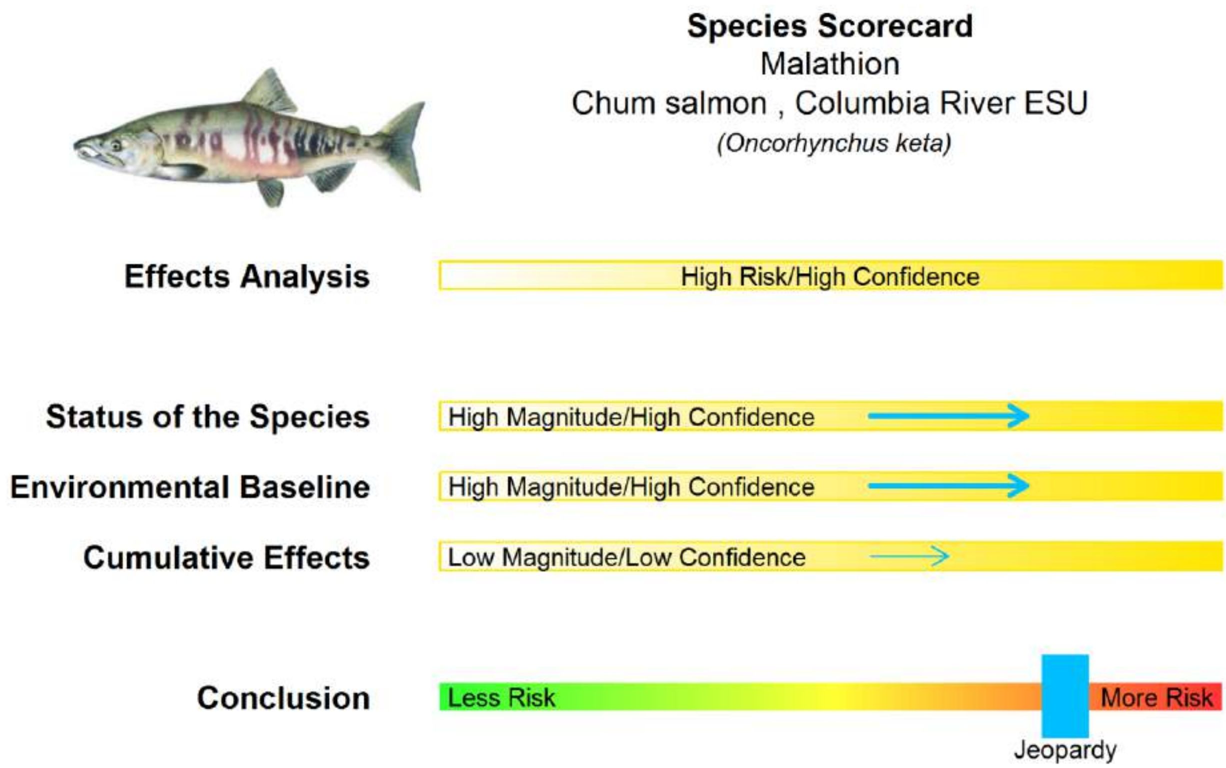

Figure 5. Species Score Card; Chum salmon, Columbia River ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and nearshore areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Declining abundance trends, high risk of extinction
- Threatened species; 7 of 16 populations are functionally extinct
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Minimal increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures anticipated in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas that may affect species

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

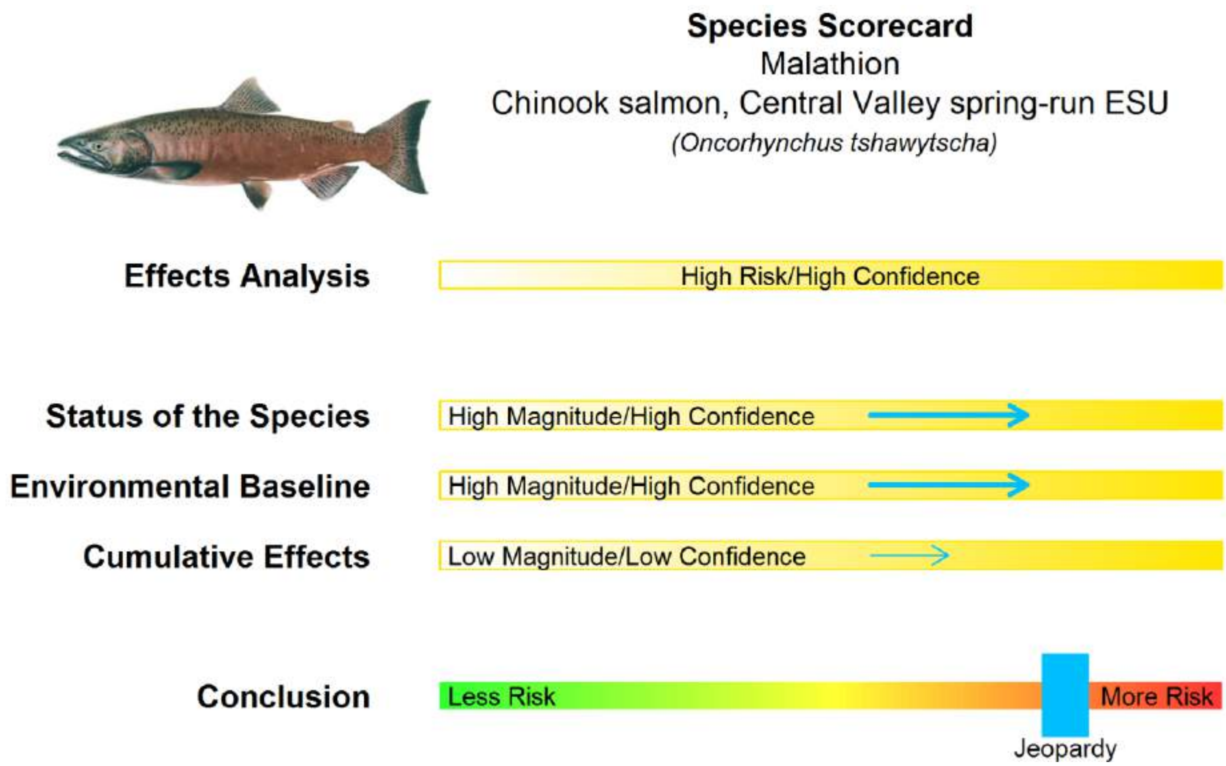

Figure 6. Species Score Card; Chinook salmon, Central Valley spring-run ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Stable to declining abundance trends, low abundances and fragmented populations
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

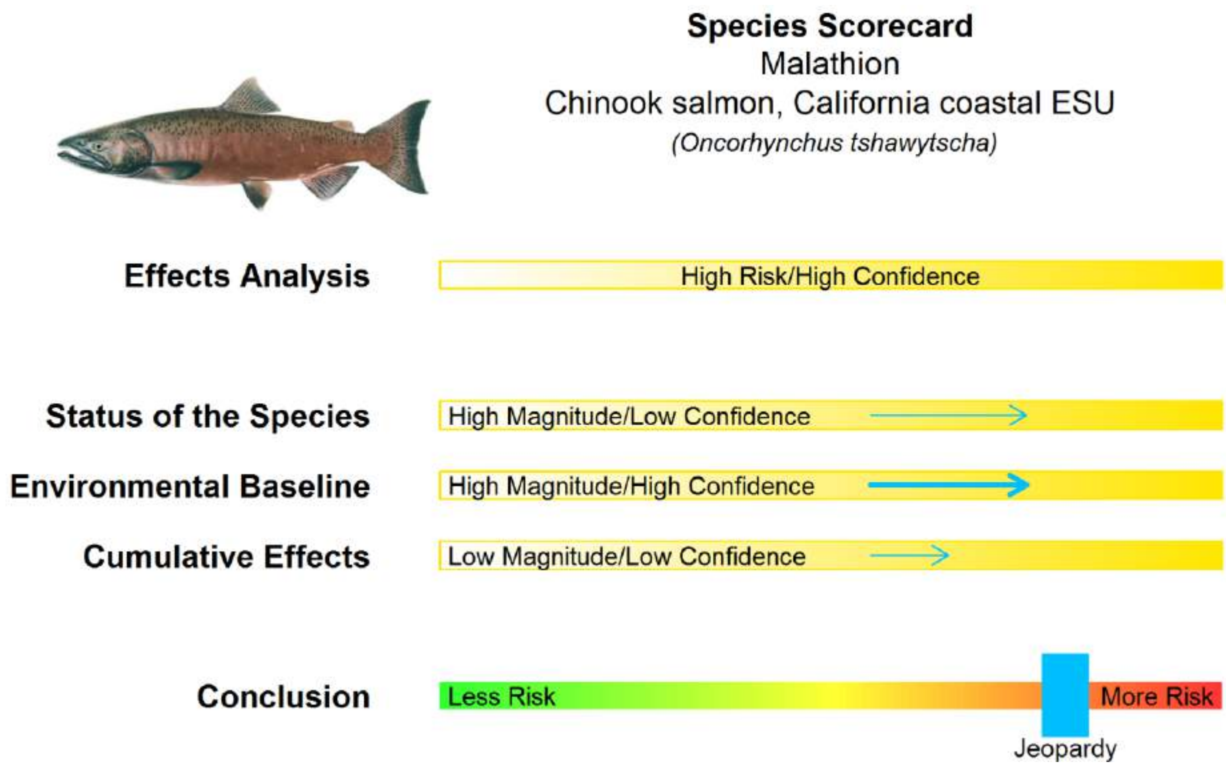

Figure 7. Species Score Card; Chinook salmon, California coastal ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Minimal increased risk of jeopardy; High magnitude/ Low confidence</u>

- One population with greater than 1000 spawners, declining trends in abundance
- Threatened
- Some recovery criteria not met, yet reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

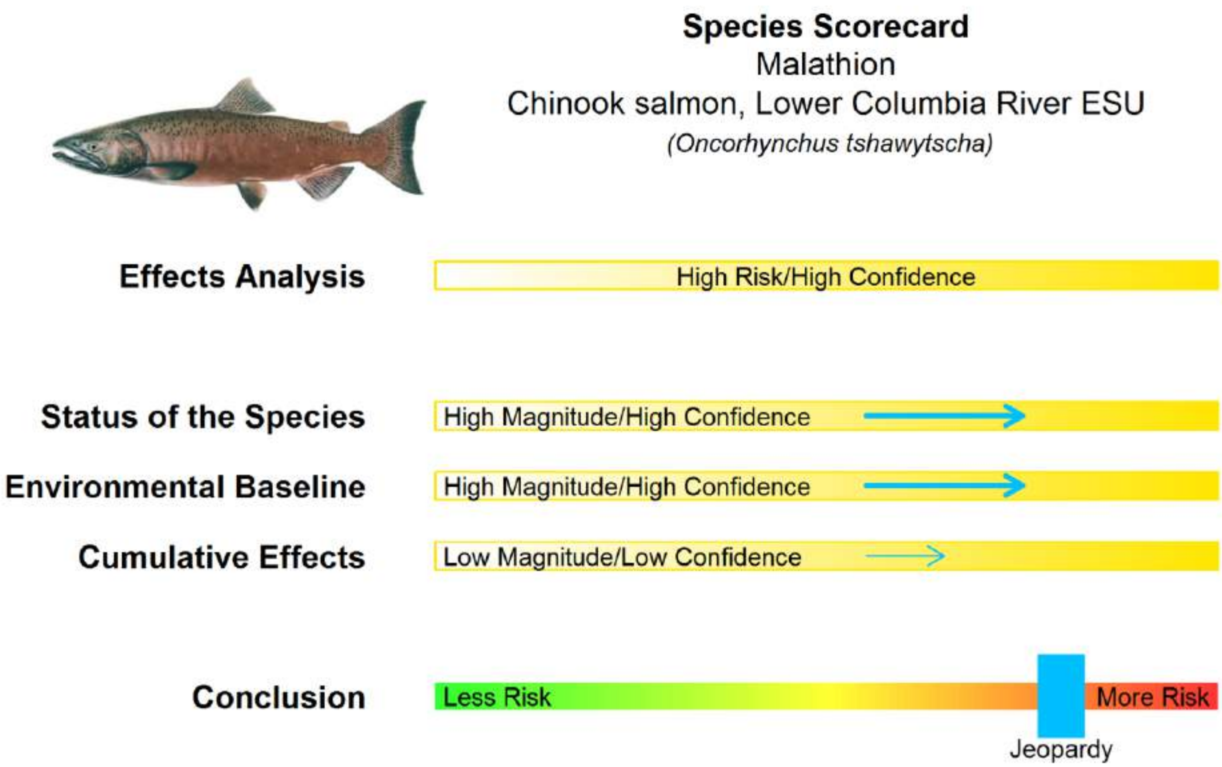

Figure 8. Species Score Card; Chinook salmon, Lower Columbia River ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Declining trends in abundance, one self-sustaining population, low genetic diversity
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Malathion is likely to jeopardize the continued existence of this species: Jeopardy**</u>

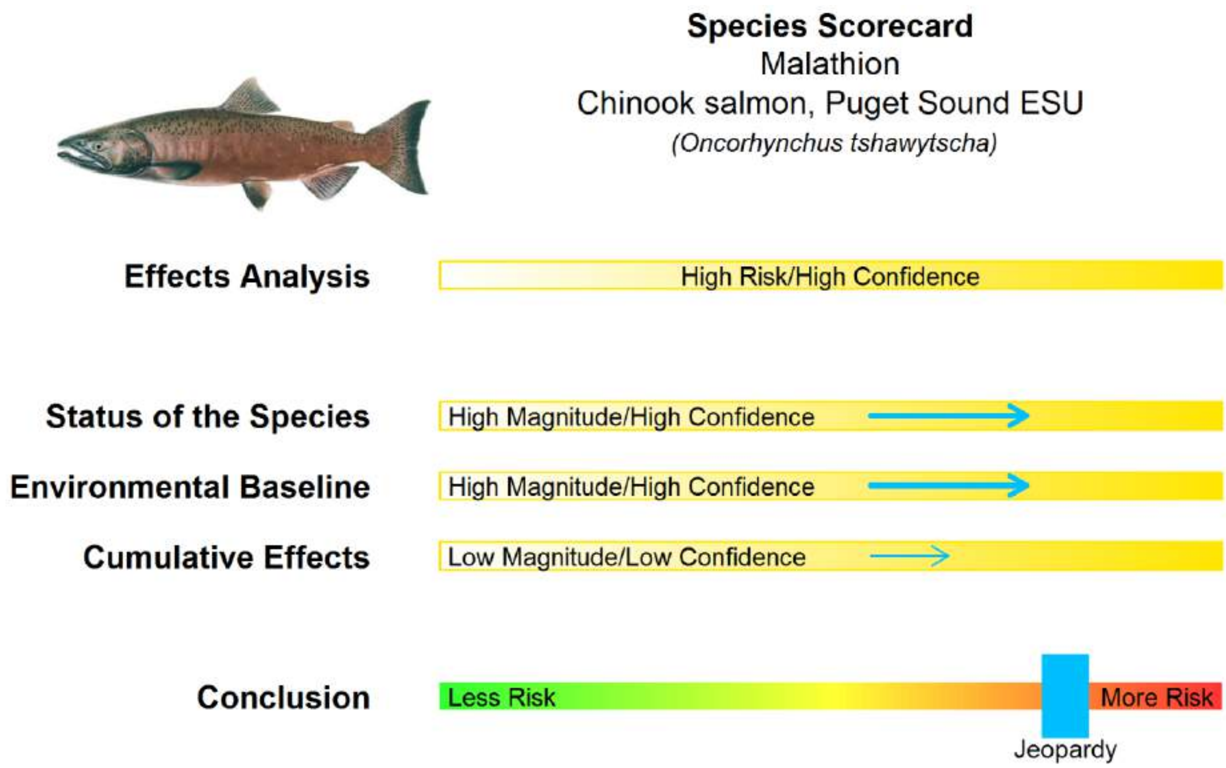

Figure 9. Species Score Card; Chinook salmon, Puget Sound ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Half of the populations declining and half increasing in abundance
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

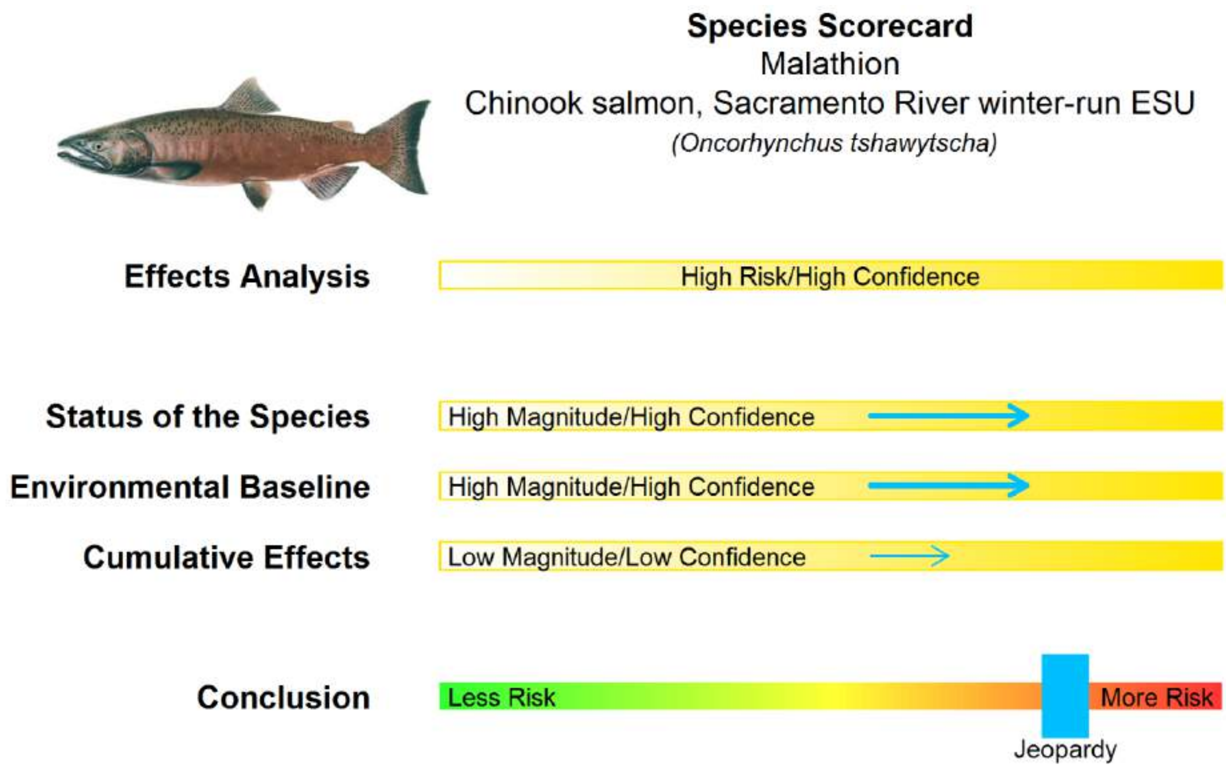

Figure 10. Species Score Card; Chinook salmon, Sacramento River winter-run ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- One extant population, declining abundance trends, hatchery-supported
- Endangered species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

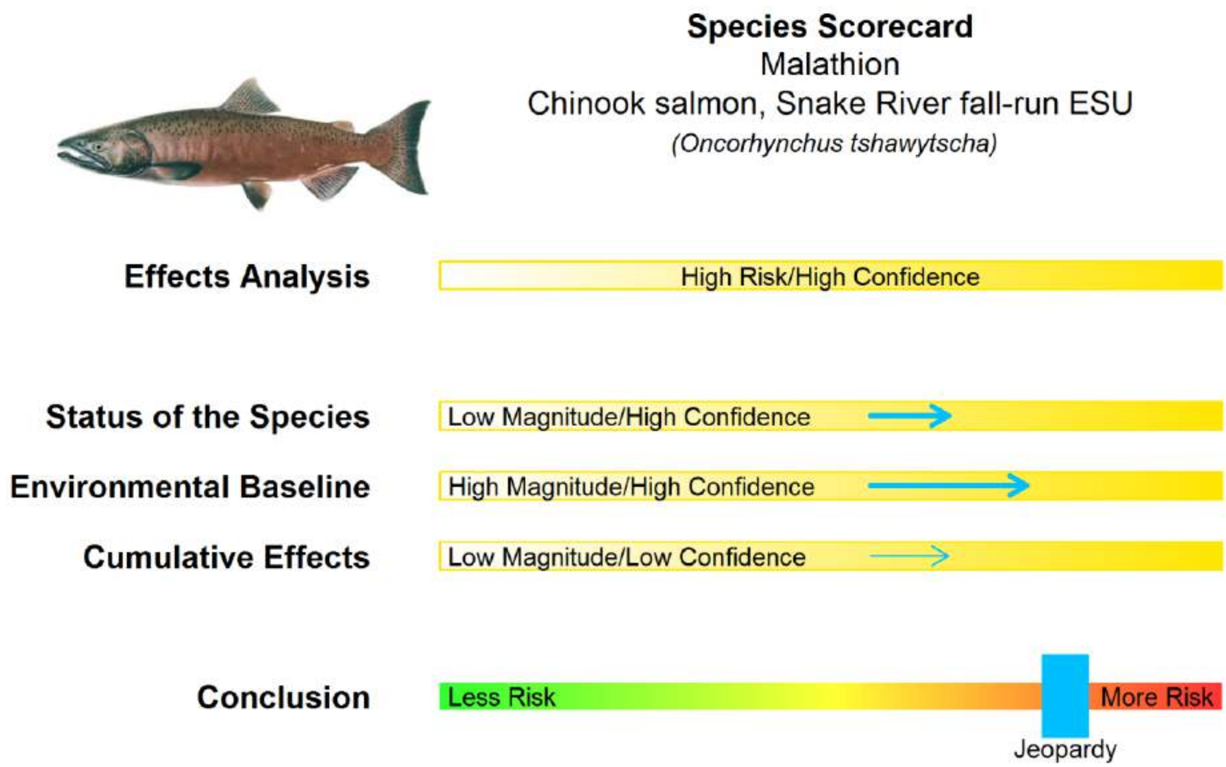

Figure 11. Species Score Card; Chinook salmon, Snake River fall-run ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence</u>

- Stable to increasing abundance trends, moderate extinction risk, hatchery supported
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they spend a portion of their lives. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

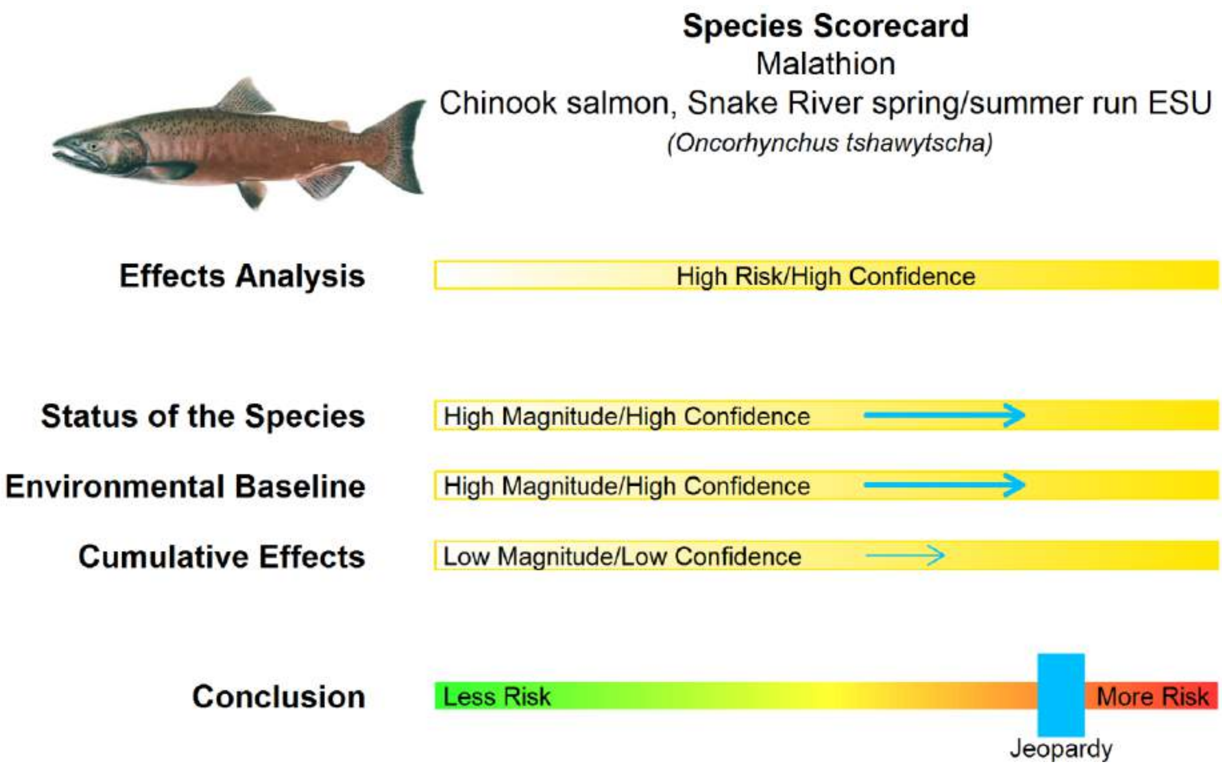

Figure 12. Species Score Card; Chinook salmon, Snake River spring/summer run ESU; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; Low magnitude/ High confidence

- Decreasing abundance trends, high extinction risk, moderate genetic diversity
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

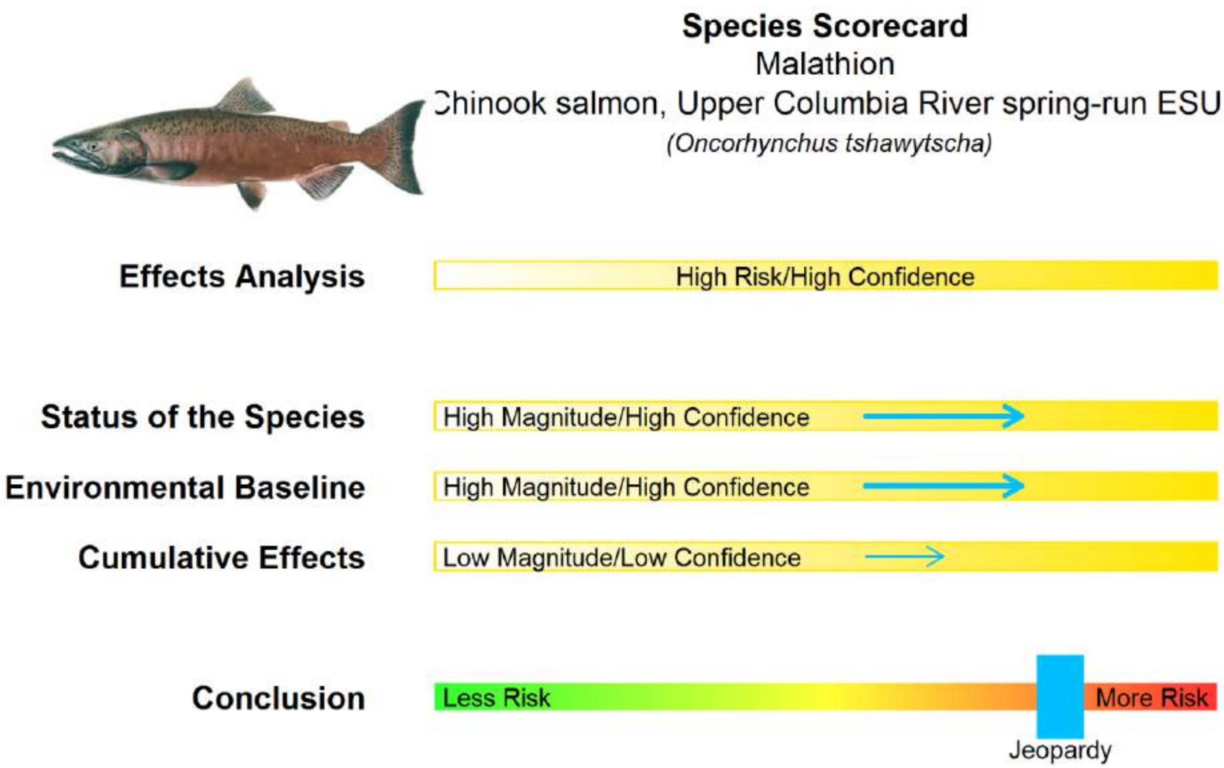

Figure 13. Species Score Card; Chinook salmon, Upper Columbia River spring-run ESU; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Decreasing abundance trends, independent populations not replacing themselves
- Endangered species (all independent population experiencing low abundance)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

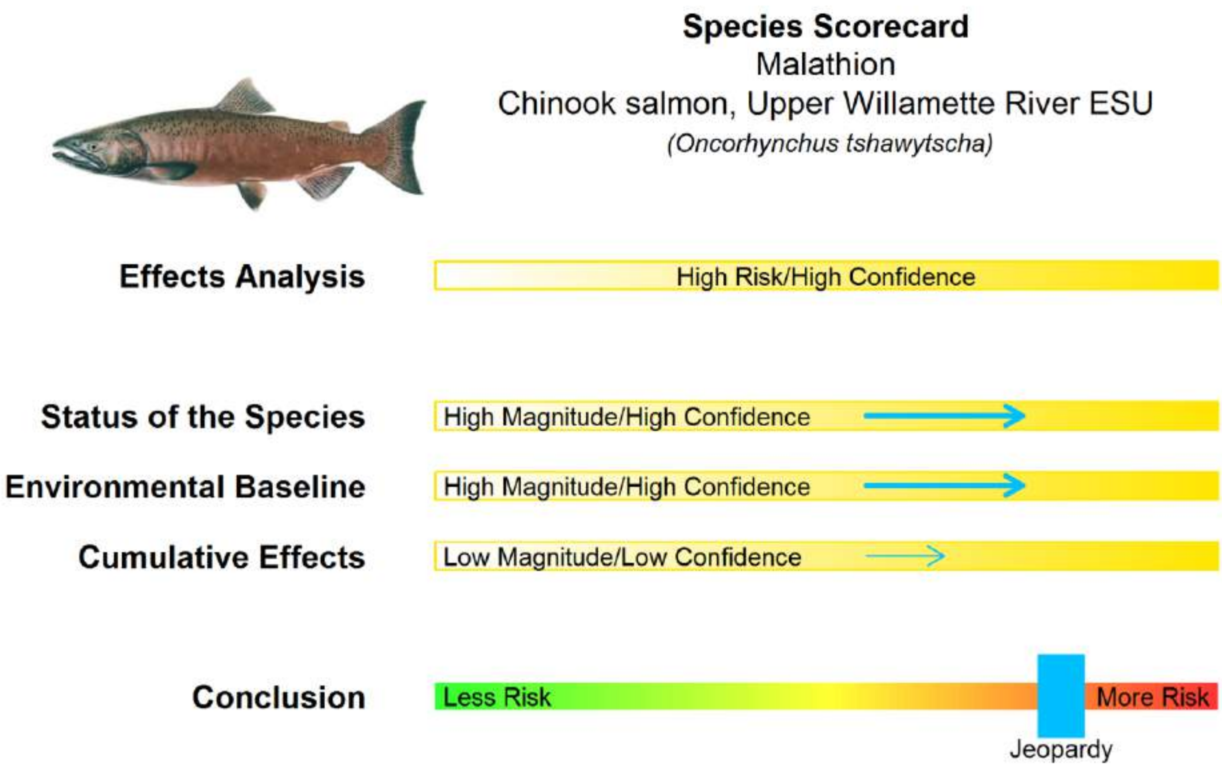

Figure 14. Species Score Card; Chinook salmon, Upper Willamette River ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; How magnitude/ High confidence</u>

- Decreasing abundance trends, 1 of 7 remaining naturally reproducing populations
- Threatened species
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy</u>

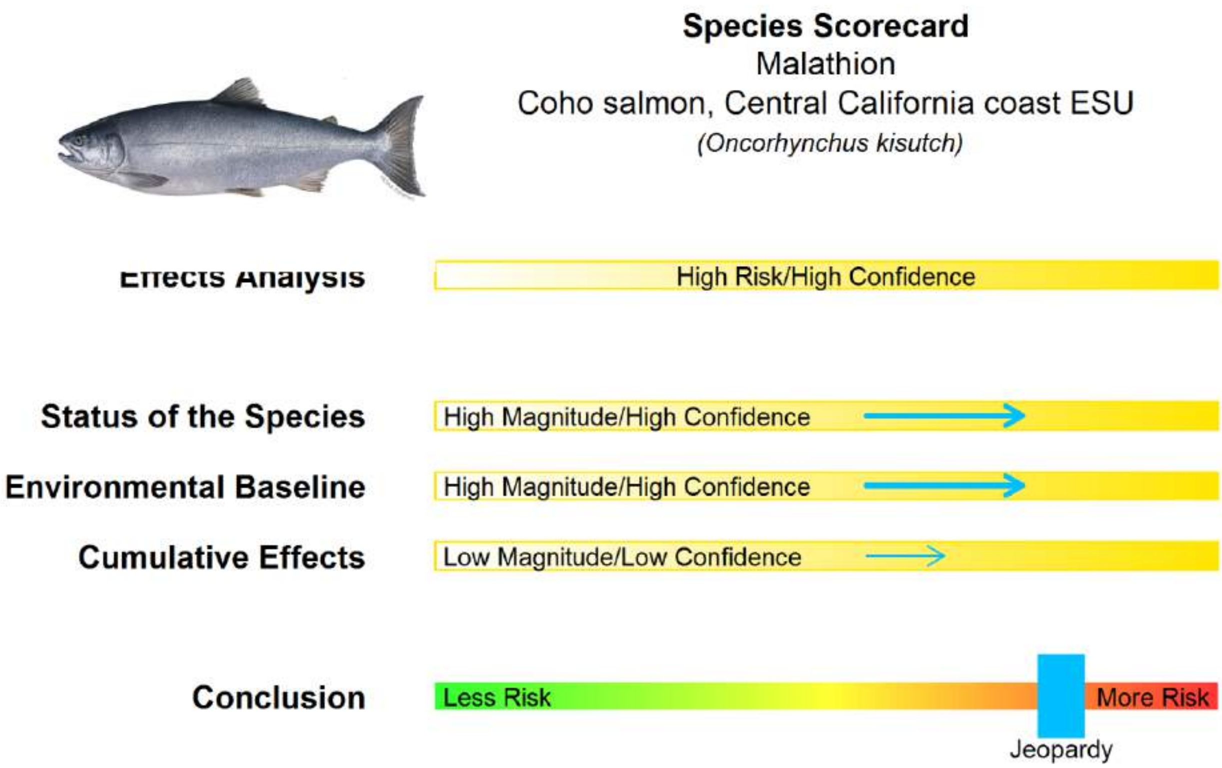

Figure 15. Species Score Card; Coho salmon, Central California coast ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; How magnitude/ High confidence</u>

- Stable population trend, fragmented populations, supported by hatchery propogation
- Endangered species (low abundances)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

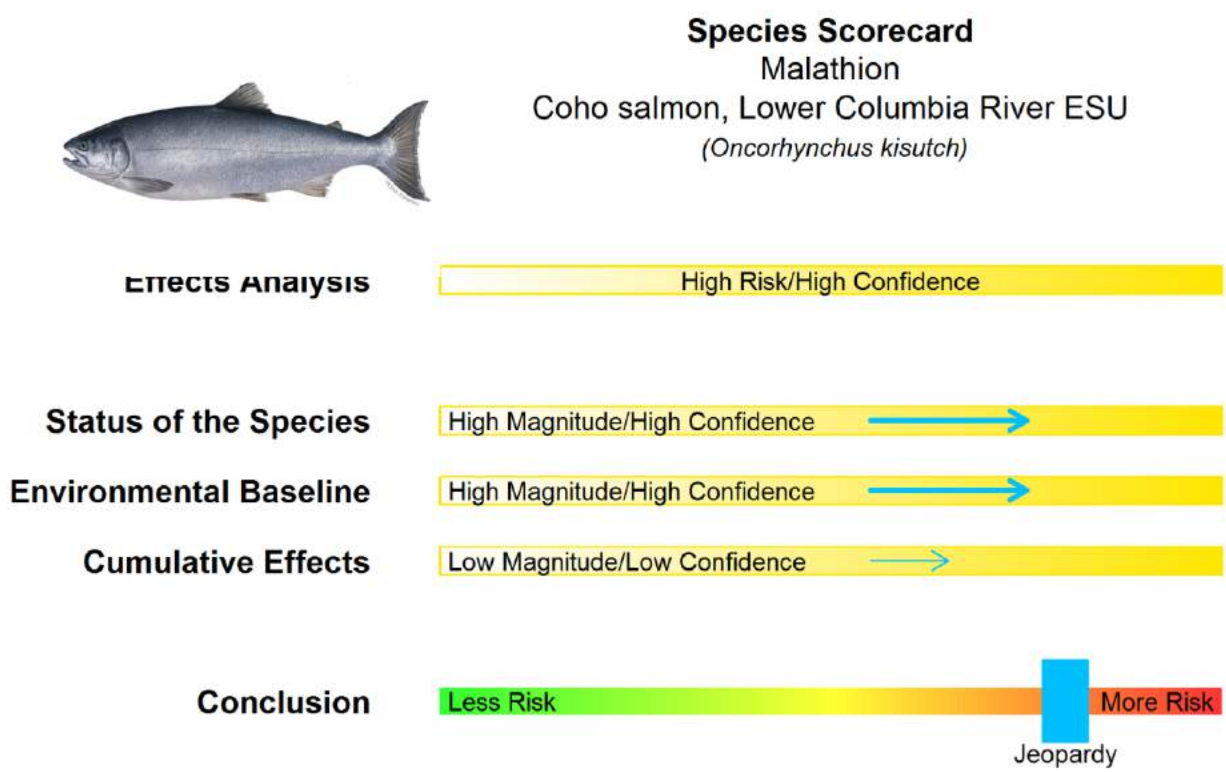

Figure 16. Species Score Card; Coho salmon, Lower Columbia River ESU; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; How magnitude/ High confidence

- Negative long/short term lambda projections; 2/25 populations exhibit natural production. Diveristy at high risk category.
- Endangered species (90% reduction in abundance of all independent populations)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

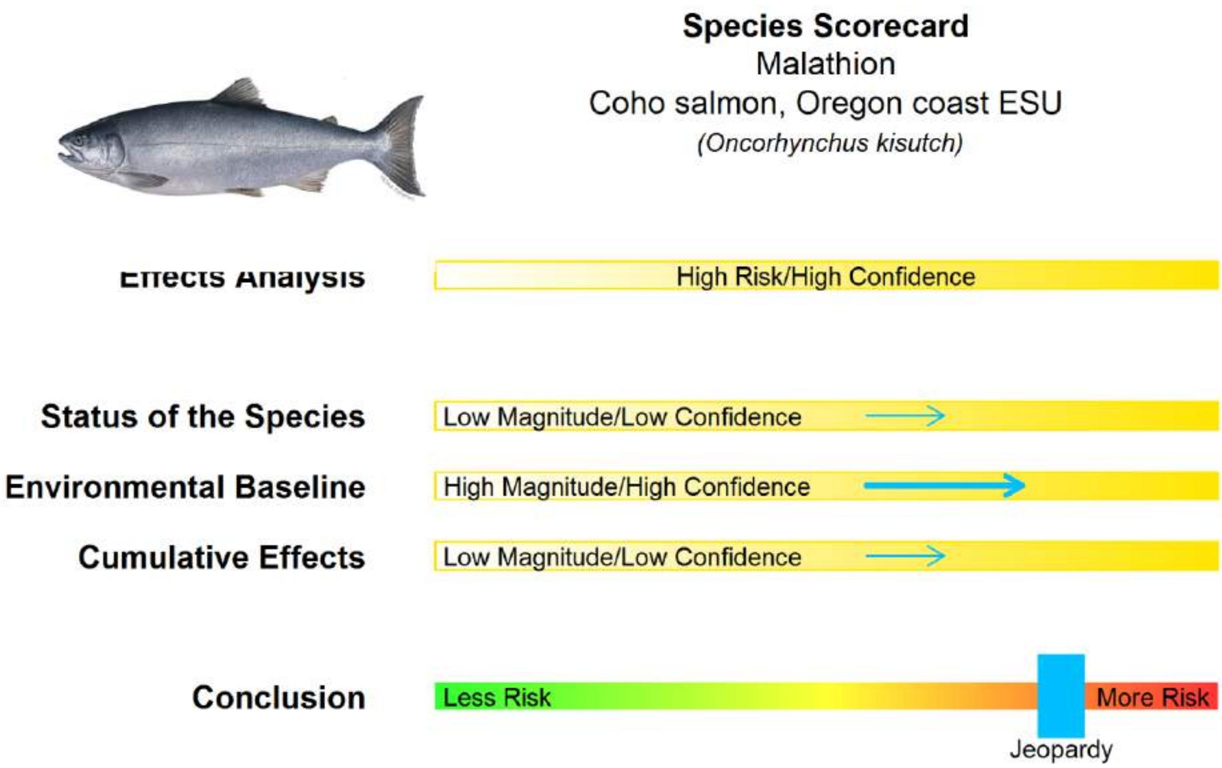

Figure 17. Species Score Card; Coho salmon, Oregon coast ESU; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Variable abundances with periods of severe declines. Negative long term trends negative
- Threatened (Severe reductions in ESU abundance compared to historical estimates)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Chlorpyrifos is likely to jeopardize the continued existence of this species: Jeopardy

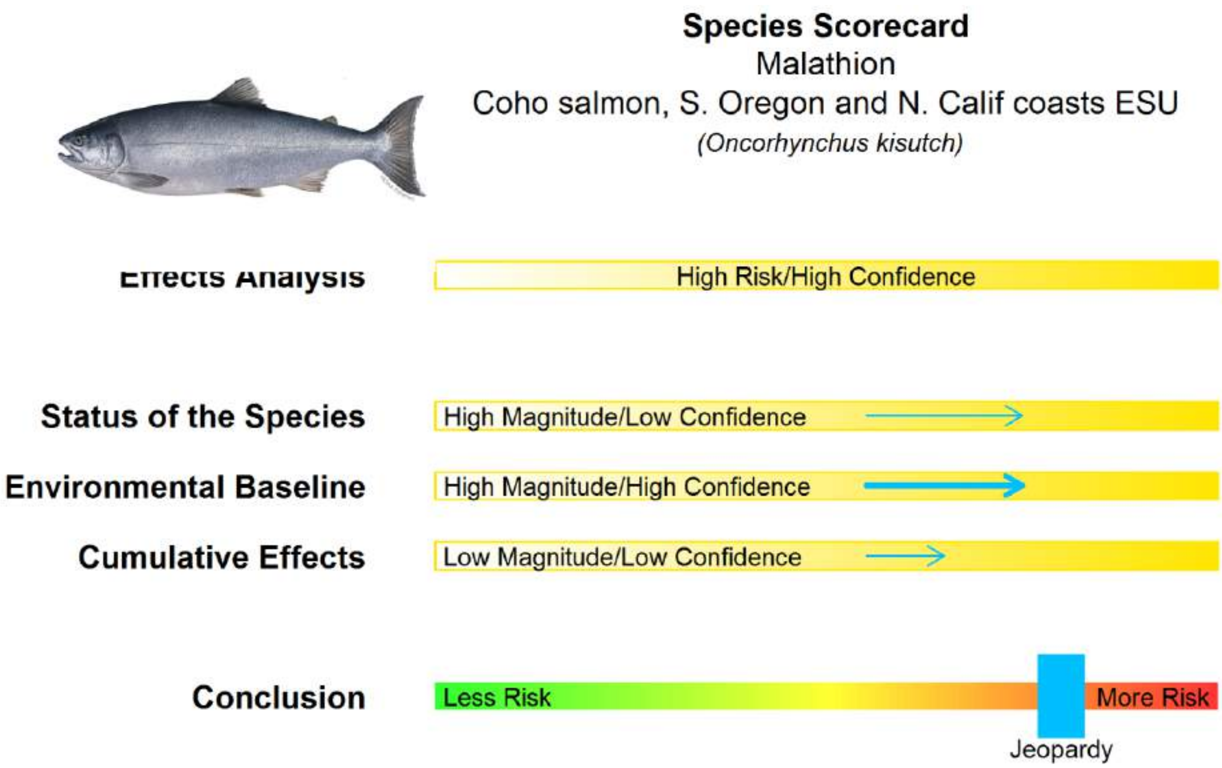

Figure 18. Species Score Card; Coho salmon, S. Oregon and N. Calif coasts ESU; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Limited data on population abundance, thus trend data unavailable
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

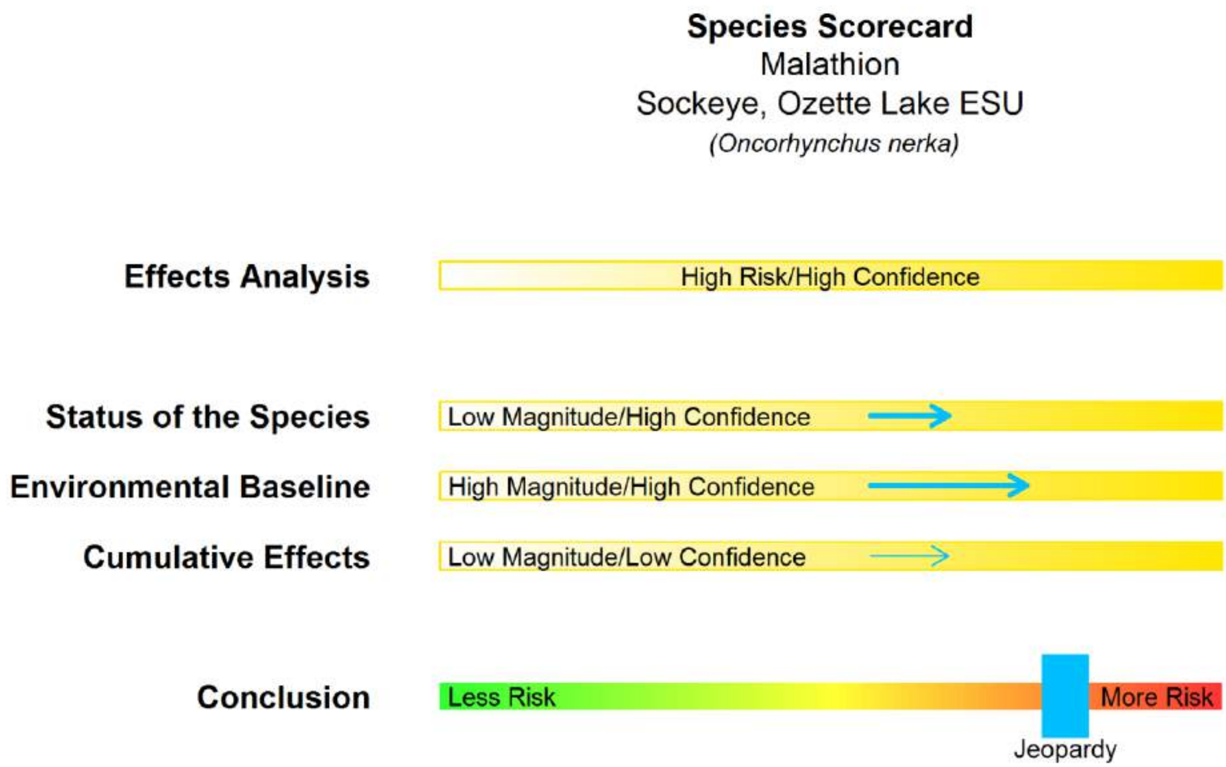

Figure 19. Species Score Card; Sockeye, Ozette Lake ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence</u>

- Stable productivity rates; low genetic diversity and low resilience to future perturbations
- Threatened (abundance only 1% of historical levels)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations predicted for freshwater habitats. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

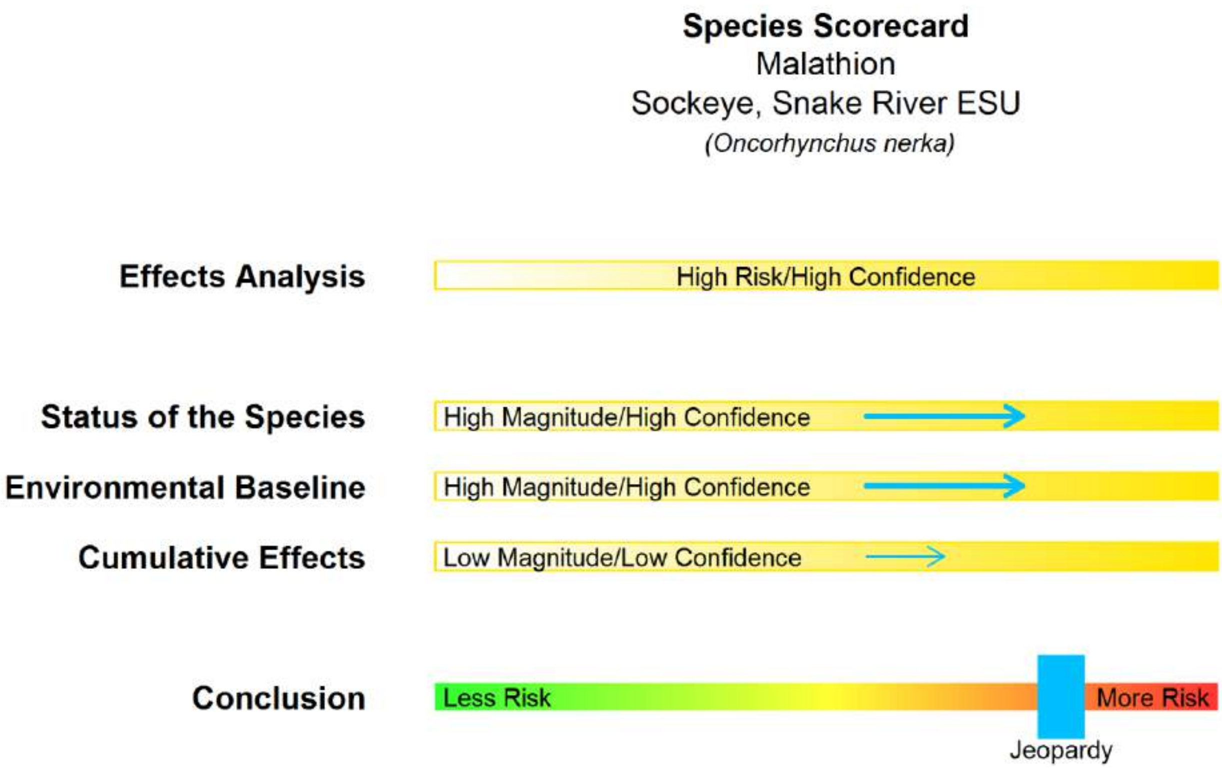

Figure 20. Species Score Card; Sockeye, Snake River ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- One population remaining supported by hatchery propagation. Increasing abundance, well below sustainable natural production. Low resilience to perturbations.
- Endangered (abundance only 1% of historical levels)
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Malathion is likely to jeopardize the continued existence of this species: Jeopardy**</u>

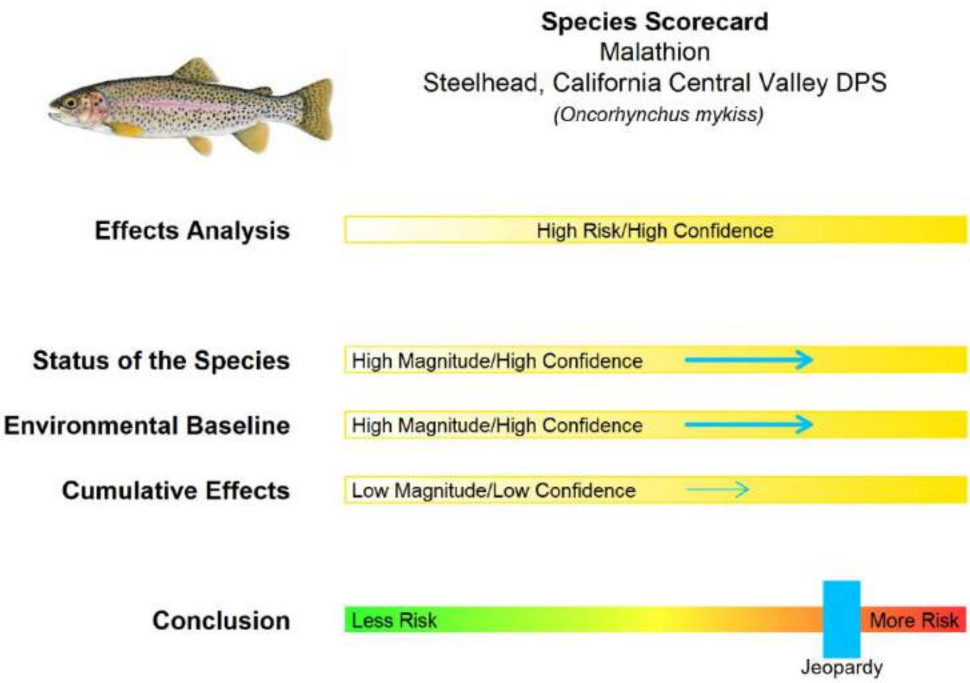

Figure 21. Species Score Card; Steelhead, California Central Valley distinct Population Segment (DPS); Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Long-term trend of declining abundances and reduced genetic diversity. Populations supplemented by hatchery propogation.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

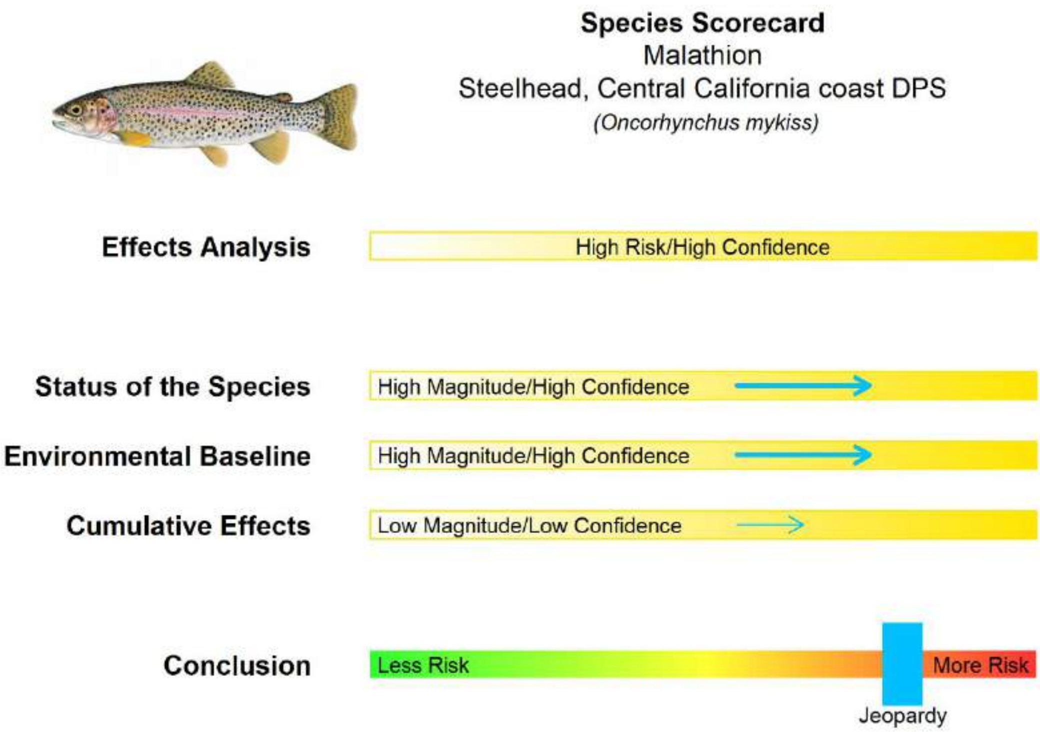

Figure 22. Species Score Card; Steelhead, Central California coast DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- 5-year population trend uncertain. Population abundance supplemented by hatchery propagation. Populations likely not viable, and have lost spatial structure.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

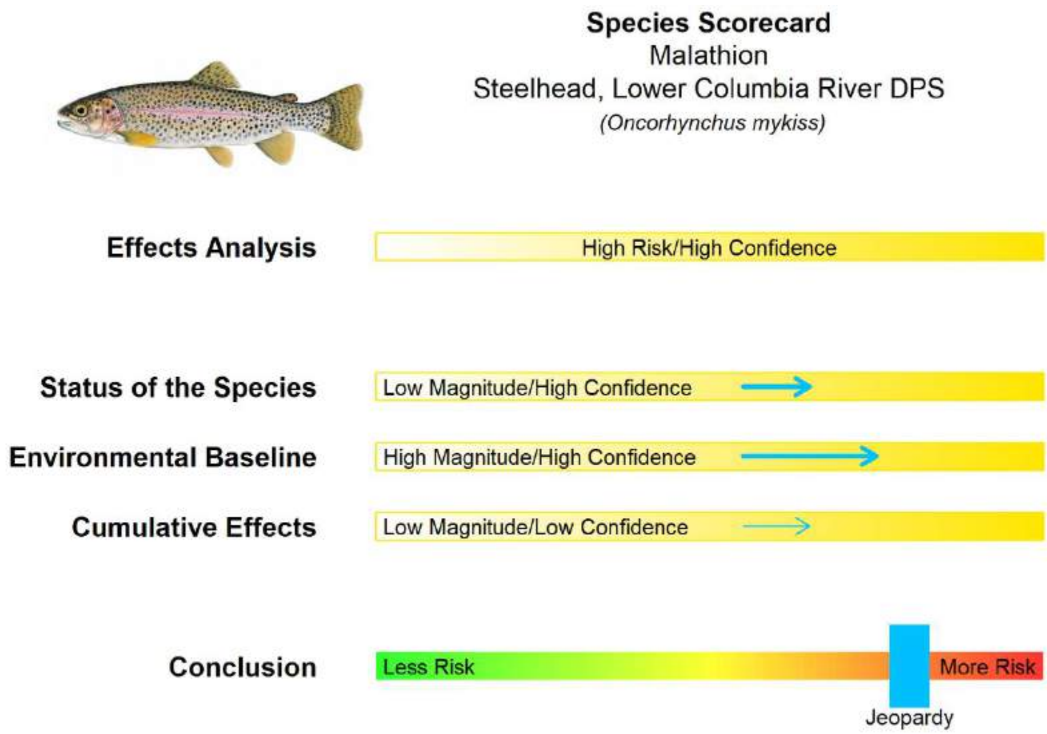

Figure 23. Species Score Card; Steelhead, Lower Columbia River DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- 5-year population trend stable. Populations exhibit low genetic diversity and impacted by a loss of available habitat.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

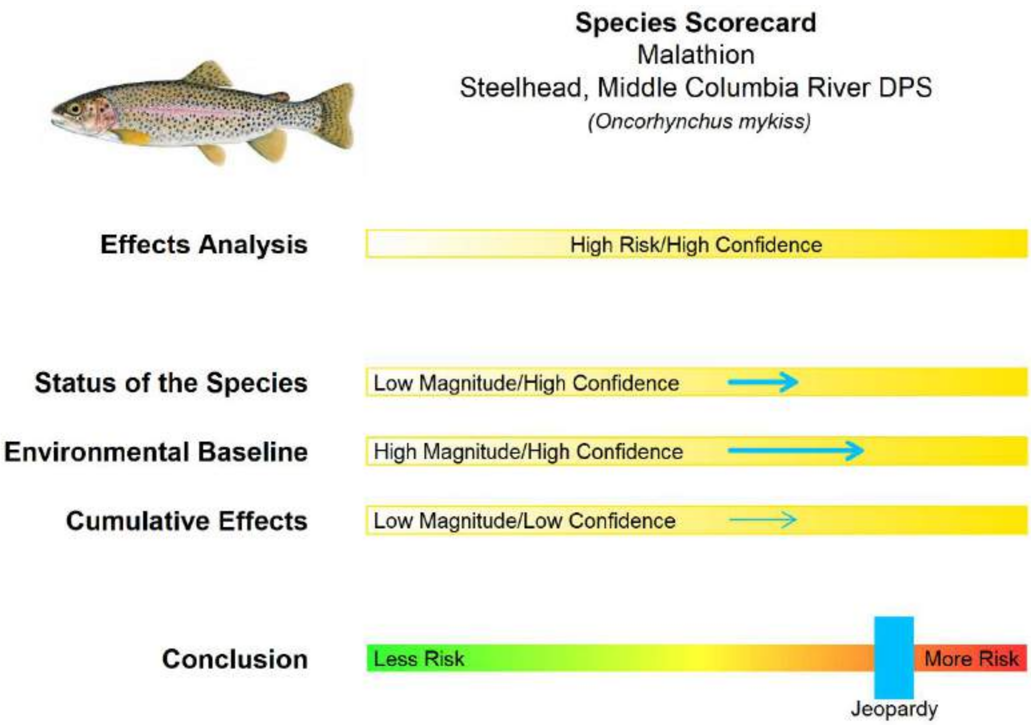

Figure 24. Species Score Card; Steelhead, Middle Columbia River DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- 5-year population trend stable to improving; abundances remain low compared to historical numbers
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

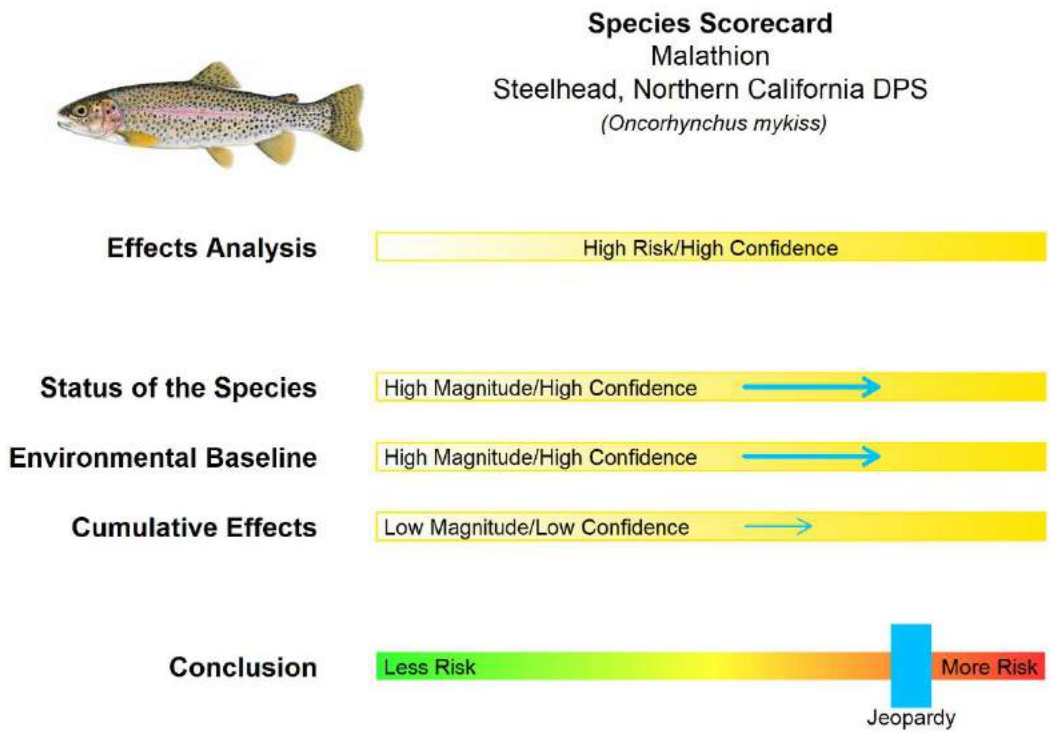

Figure 25. Species Score Card; Steelhead, Northern California DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Icreased risk of jeopardy; High magnitude/ High confidence</u>

- Variable 5-year population abundance trends; Population supplemented by hatchery propagation. Populations exhibit low abundances and productivity.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

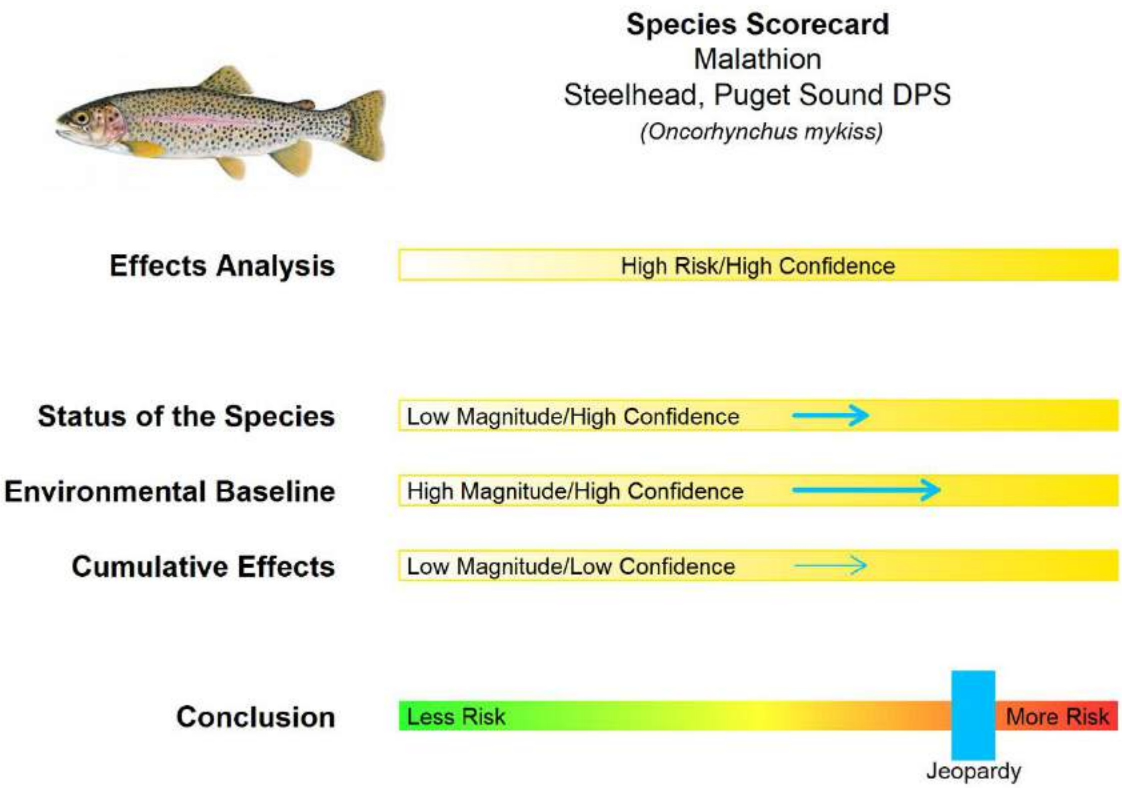

Figure 26. Species Score Card; Steelhead, Puget Sound DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- 5-year population trend stable, but populations have reduced genetic diversity
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

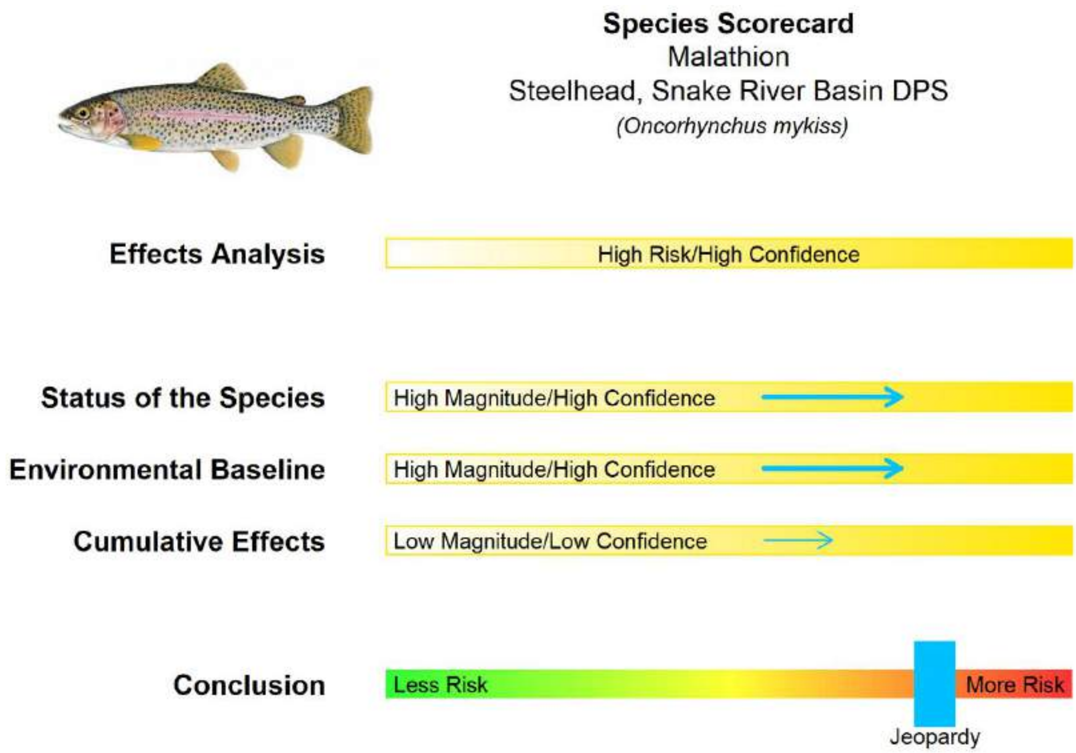

Figure 27. Species Score Card; Steelhead, Snake River Basin DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend stable to improving, but still in moderate danger of extinction. Overall abundances remain below thresholds necessary for recovery.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Malathion is likely to jeopardize the continued existence of this species: Jeopardy**</u>

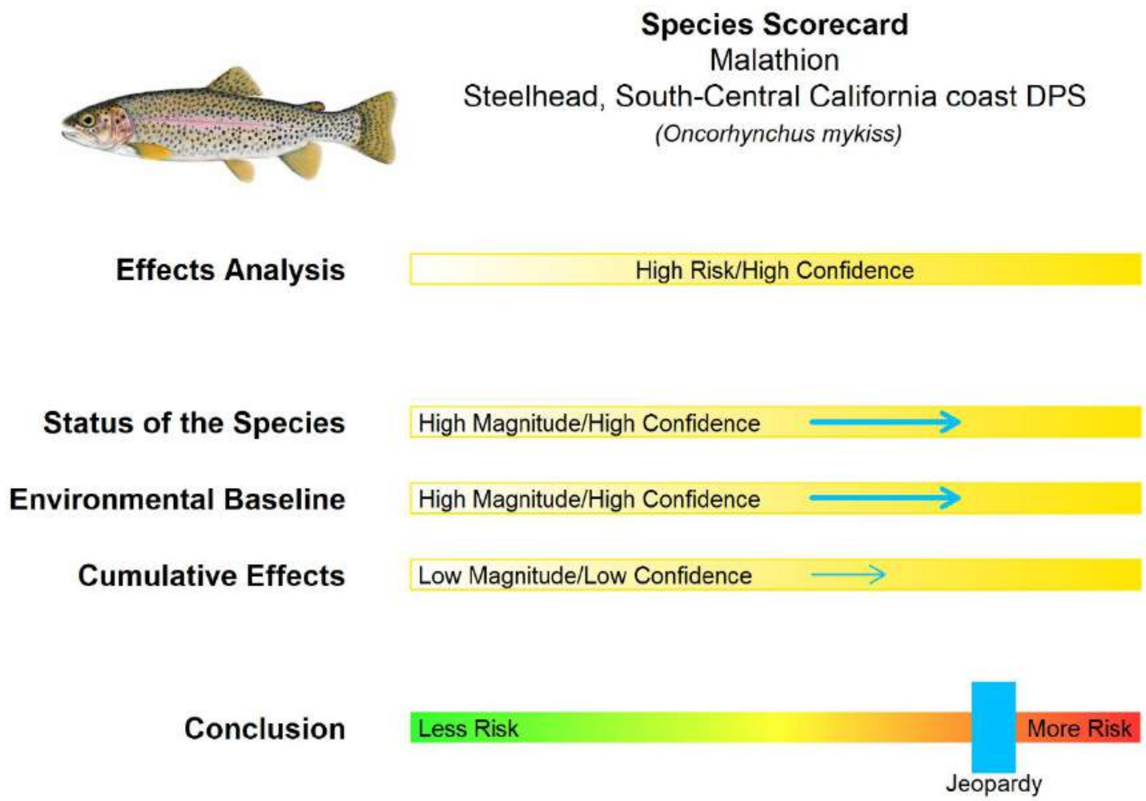

Figure 28. Species Score Card; Steelhead, South-Central California coast DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend declining, depressed abundances.
- Threatened
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

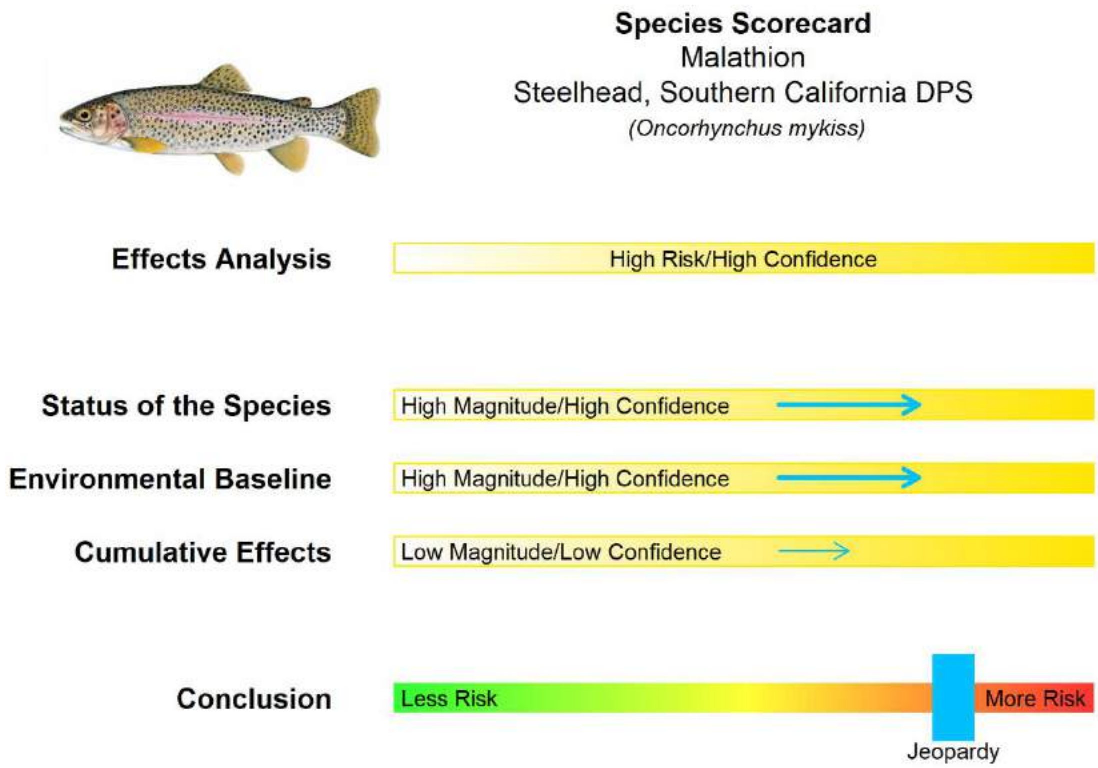

Figure 29. Species Score Card; Steelhead, Southern California DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend uncertain (large annual variations); supplemented by hatchery propagation; fragmented distributions.
- Endangered; Populations at extreme southern end of species' range
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

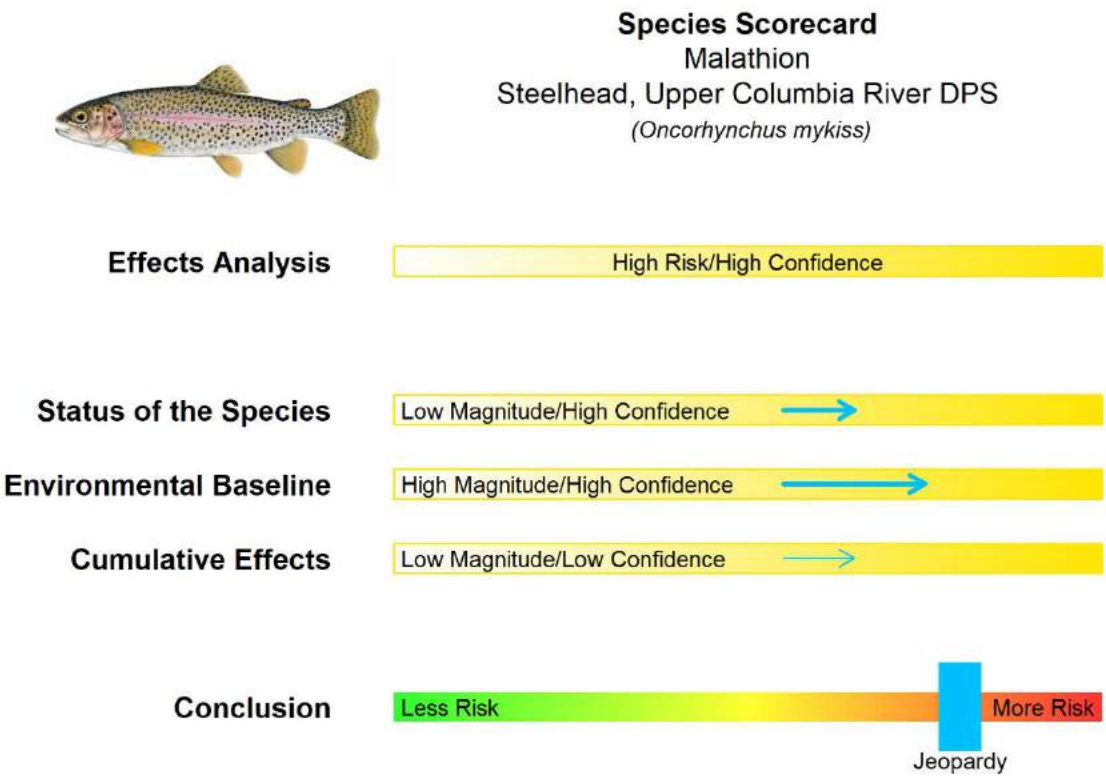

Figure 30. Species Score Card; Steelhead, Upper Columbia River DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- 5-year population trend improving, but low genetic diversity.
- Threatened;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

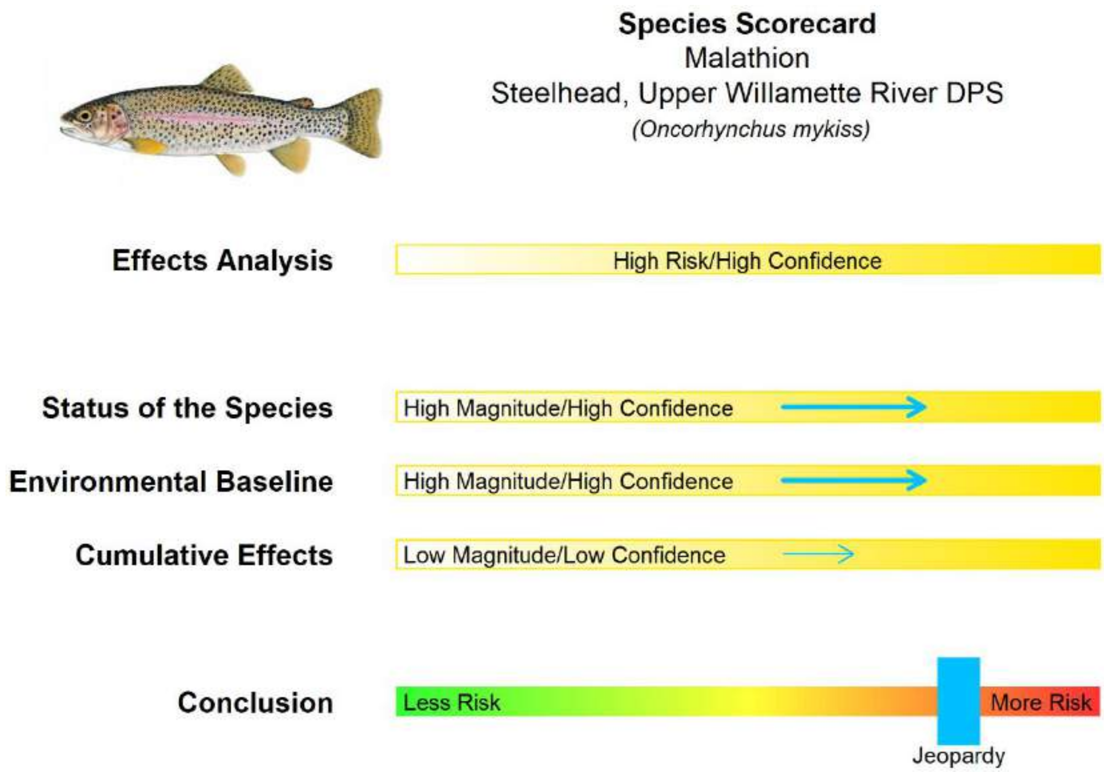

Figure 31. Species Score Card; Steelhead, Upper Willamette River DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- 5-year population trend declining, large fluctuations in abundances.
- Threatened;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

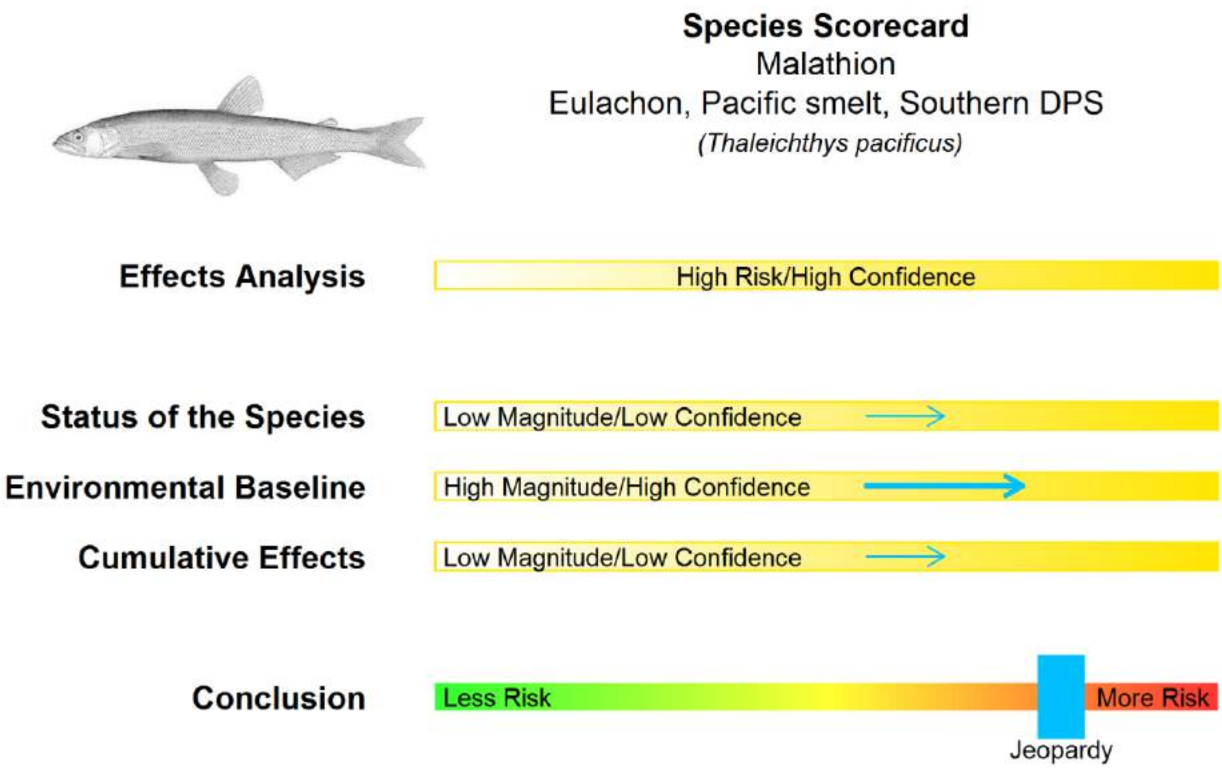

Figure 32. Species Score Card; Eulachon, Pacific smelt, Southern DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- Population abundance improving, especially in the 2013–2015 return years; in upcoming return years population declines may be widespread from poor ocean conditions
- Threatened; severely depressed abundance mid-late 1990s to late 2000s;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

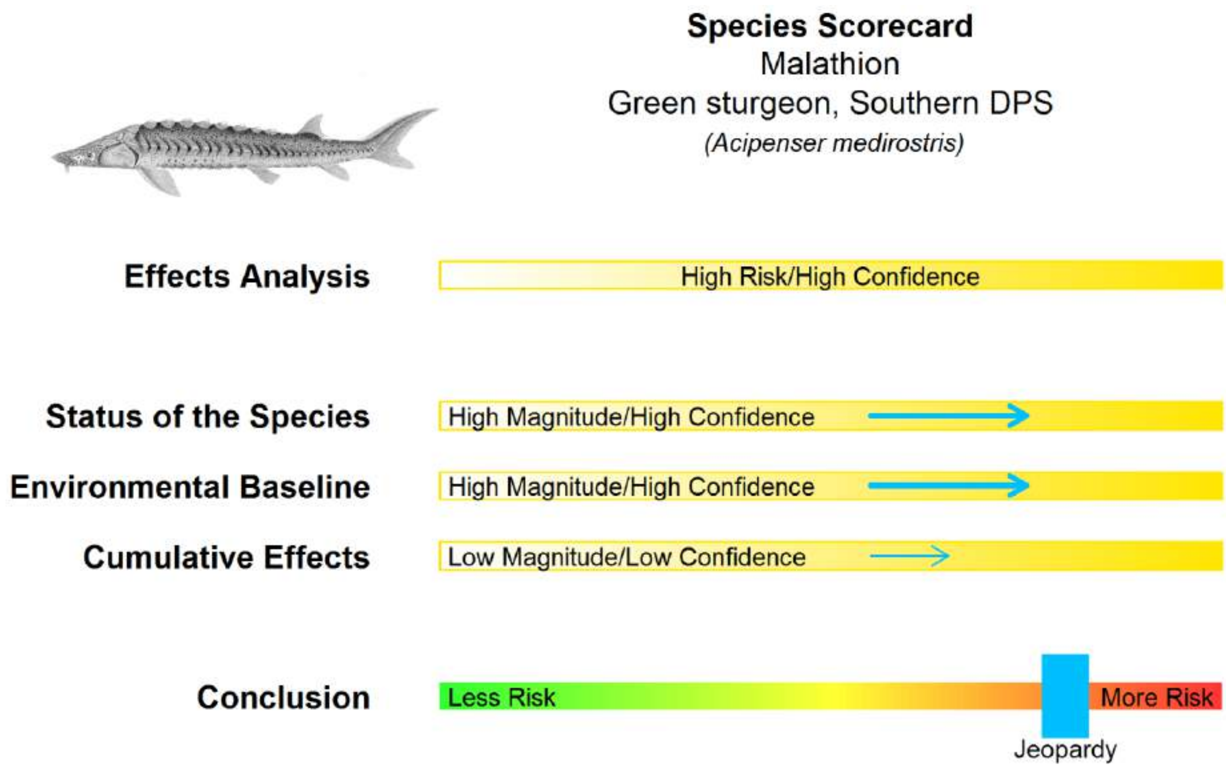

Figure 33. Species Score Card; Green sturgeon, Southern DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Small population size, little population data, few remaining spawning sites
- Threatened;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Increased risk of jeopardy; High magnitude/ High confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

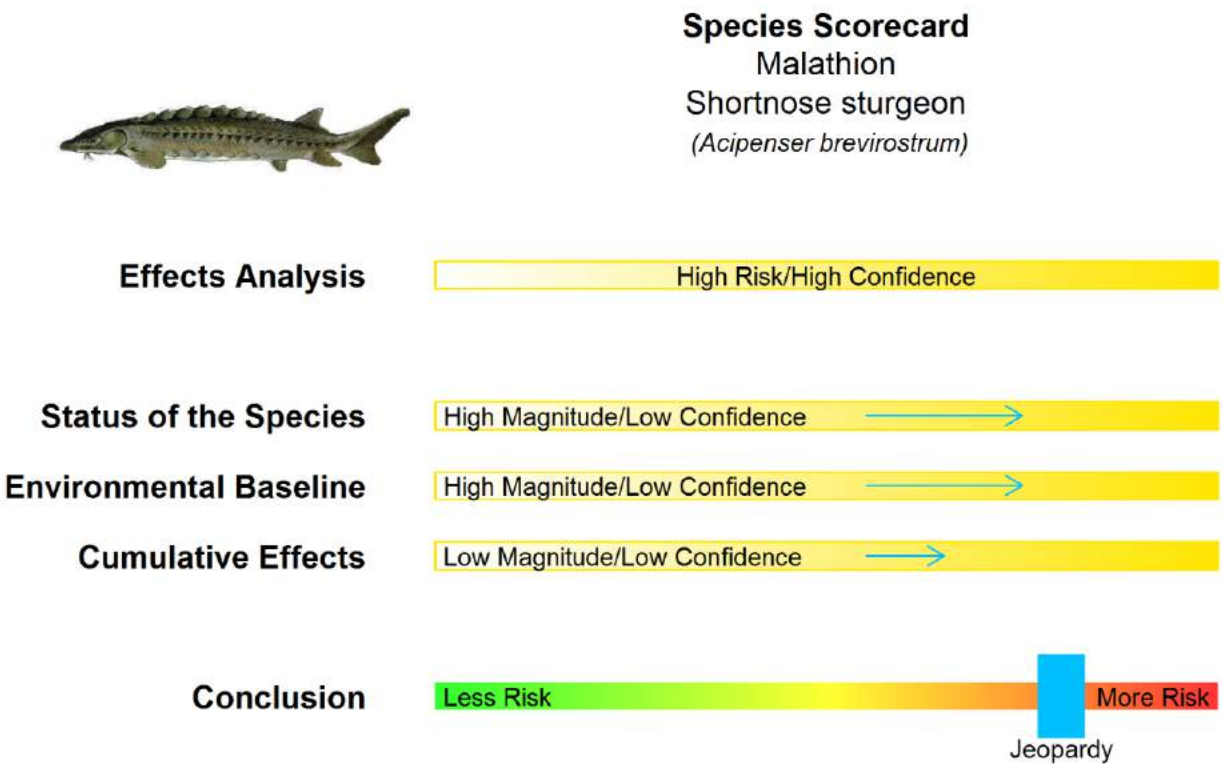

Figure 34. Species Score Card; Shortnose sturgeon; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence</u>

- Stable to increasing populations, fragmented populations, only 12 known spawning sites
- Endangered;
- Recovery criteria not identified

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Malathion is likely to jeopardize the continued existence of this species: Jeopardy**</u>

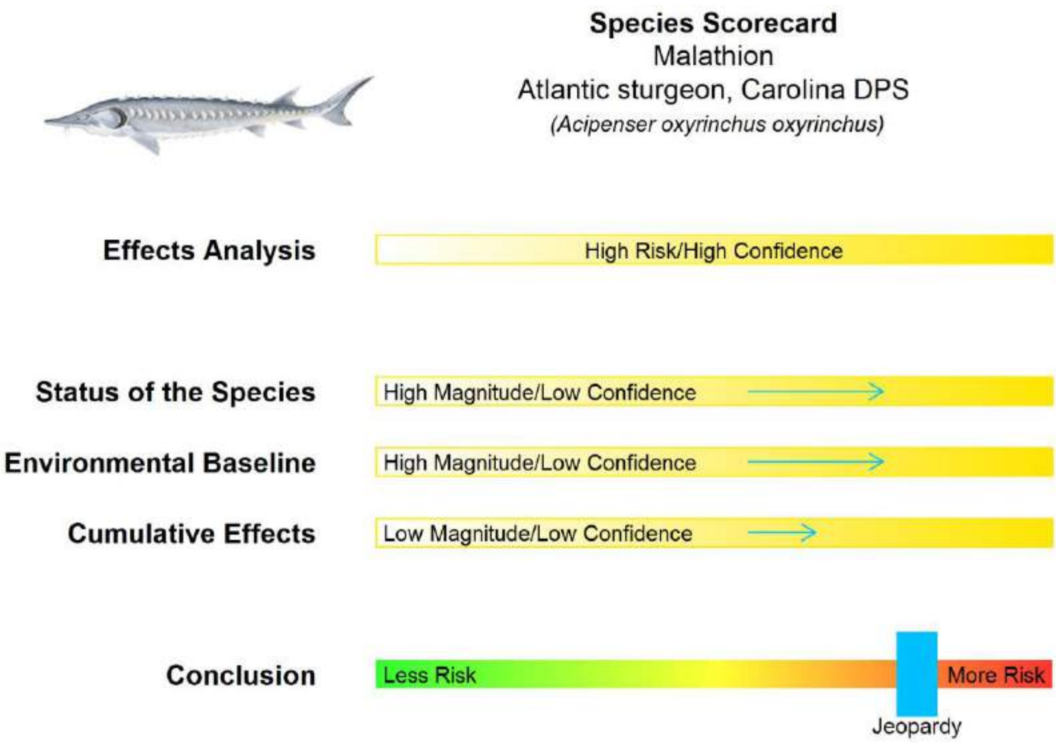

Figure 35. Species Score Card; Atlantic sturgeon, Carolina DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence

- <3% of historical abundance
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

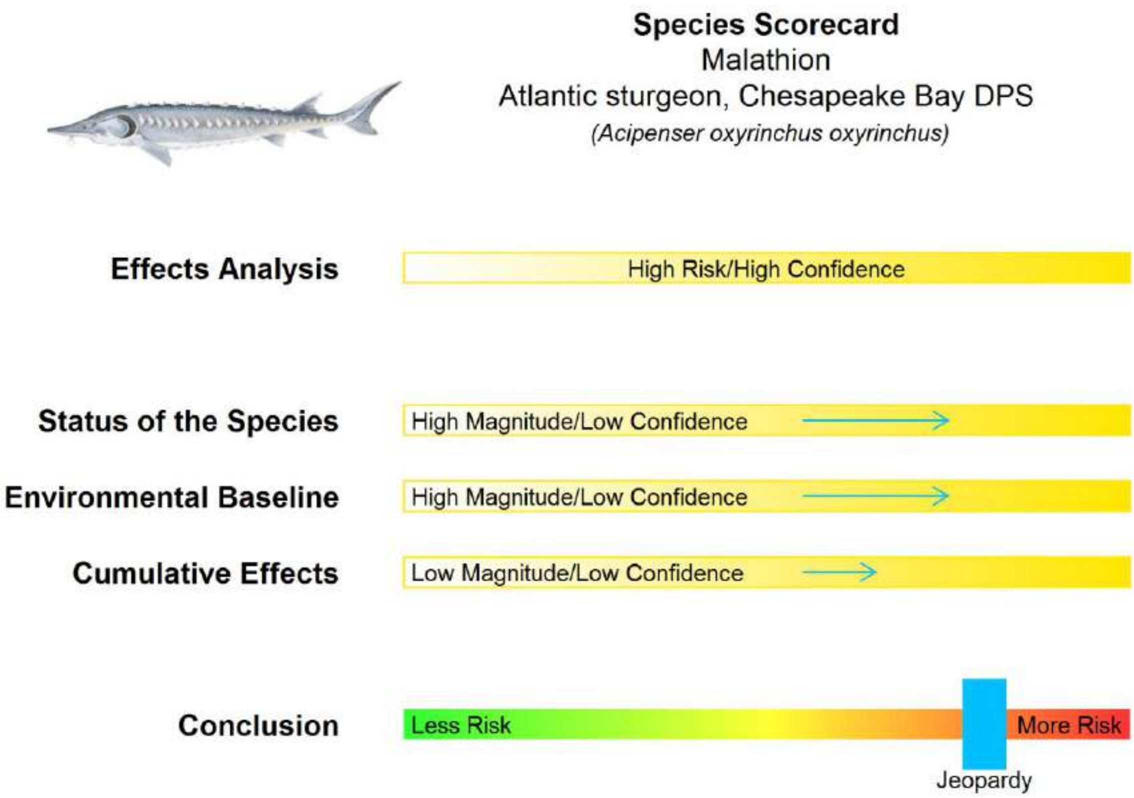

Figure 36. Species Score Card; Atlantic sturgeon, Chesapeake Bay DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence

- 4% of historical abundance, unknown population growth rate
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

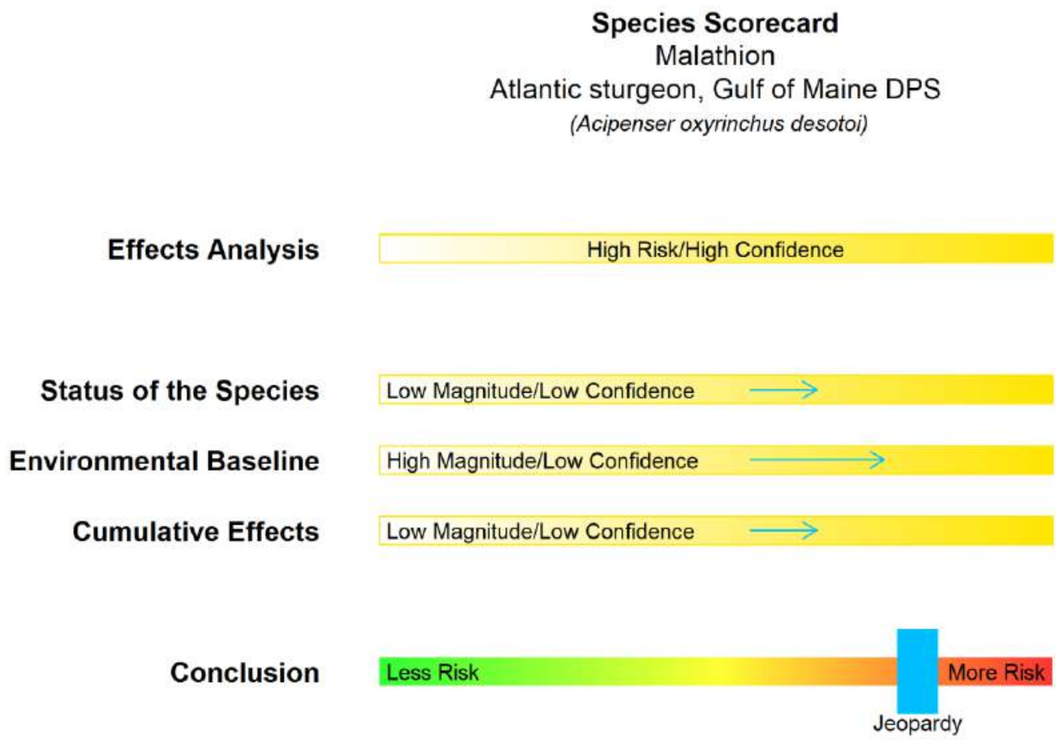

Figure 37. Species Score Card; Atlantic sturgeon, Gulf of Maine DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: minimal increased risk of jeopardy; Low magnitude/ low confidence</u>

- 10% of historical abundance, unknown population growth rate, range expanding
- Threatened;
- Recovery criteria not identified

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

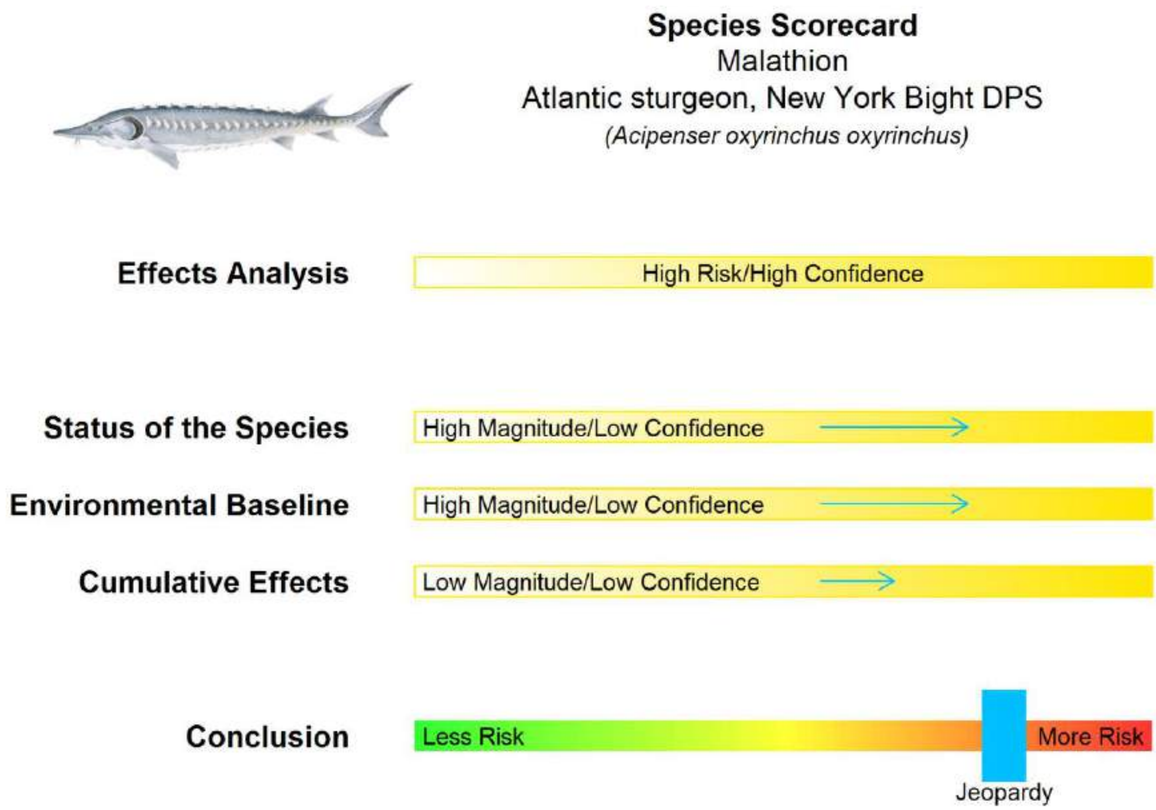

Figure 38. Species Score Card; Atlantic sturgeon, New York Bight DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence</u>

- 4% of historical abundance, unknown population growth rate
- Endangered;
- Recovery criteria not identified

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

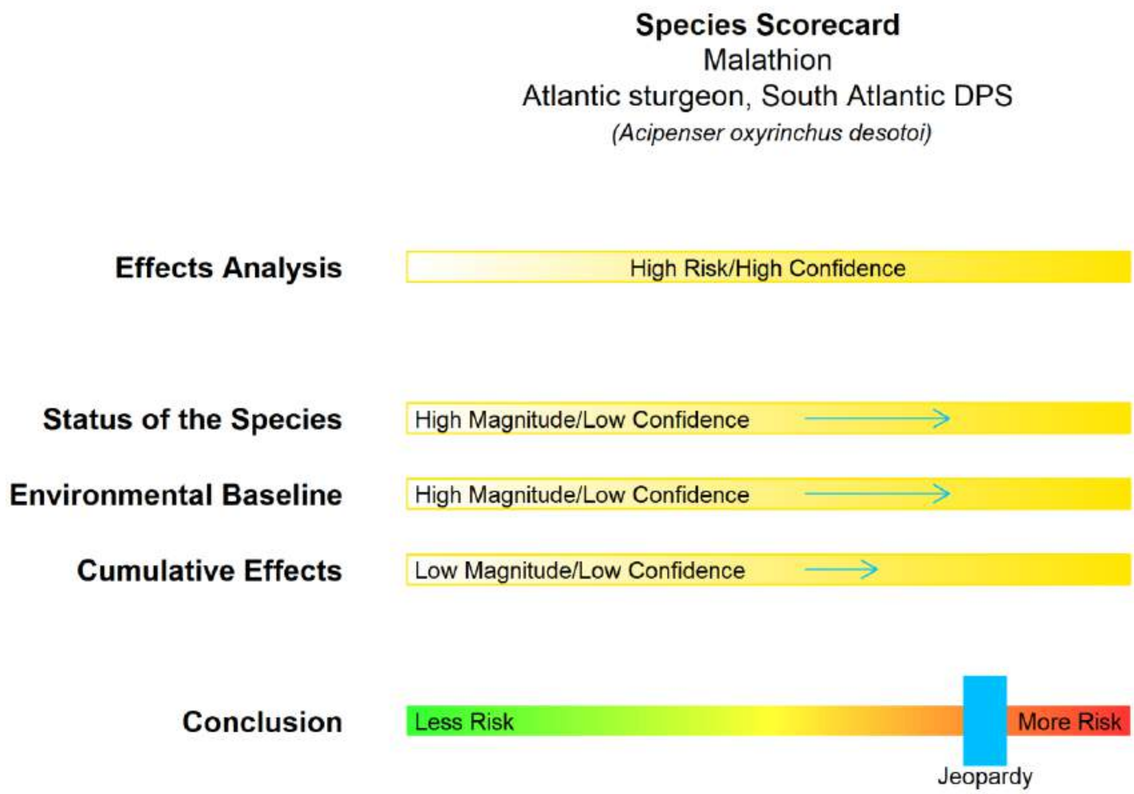

Figure 39. Species Score Card; Atlantic sturgeon, South Atlantic DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ low confidence</u>

- <6% of historical abundance
- Endangered;
- Recovery criteria not identified

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>Malathion is likely to jeopardize the continued existence of this species: Jeopardy</u>

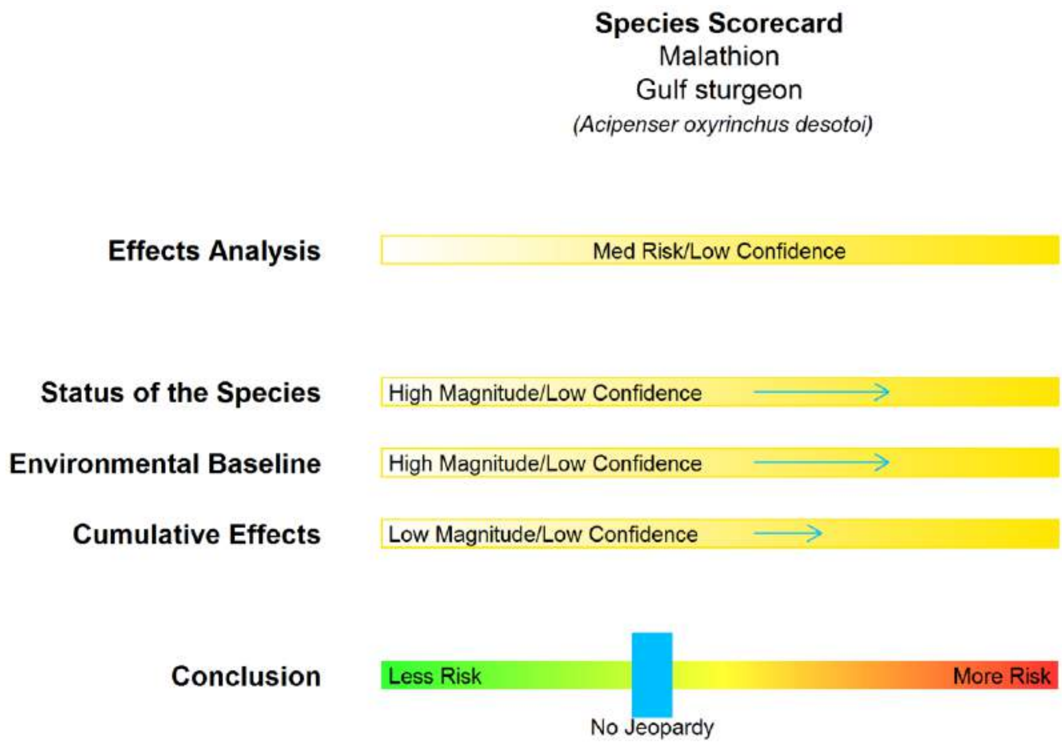

Figure 40. Species Score Card; Gulf sturgeon; Malathion

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance may occur in estuarine areas
- Potential effects include death, reduced cholinesterase activity, reduced growth and prey abundance, and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Eastern range populations stable to increasing, western population lower abundances and more uncertainty, minimal growth rate data
- Threatened;
- Recovery criteria not identified

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated to affect species
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In estuarine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in these estuarine areas where they rear. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

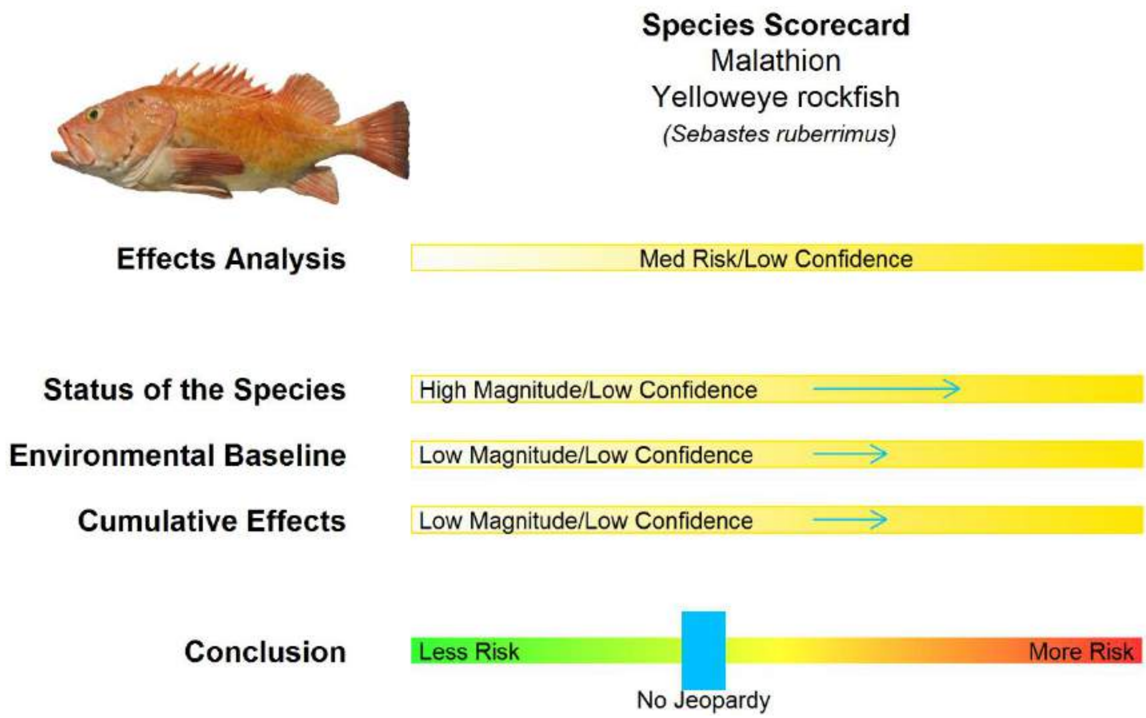

Figure 41. Species Score Card; Yelloweye rockfish; Malathion

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance may occur in marine areas
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Historically low abundance, fragmented populations, altered population age structure
- Threatened;
- Recovery criteria not identified

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures at toxic concentrations unanticipated in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations and species use of deep water habitats. The species is most at risk while in shallow surface, marine areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

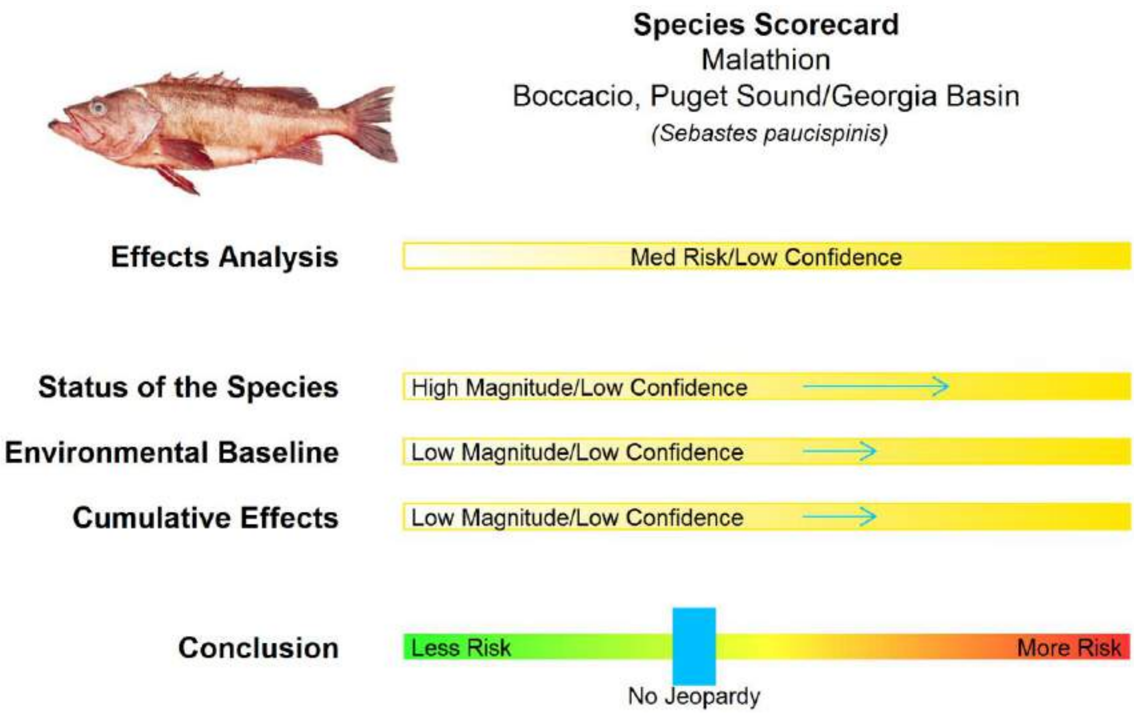

Figure 42. Species Score Card; Boccacio, Puget Sound/Georgia Basin; Malathion

Effects Analysis: Medium risk/Low confidence

- Reduced abundance may occur in marine areas
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- There are no estimates of historical or current abundance across the DPS's full range; Indices suggest declining abundance trends
- Threatened;
- Recovery criteria not identified

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas where they rear. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

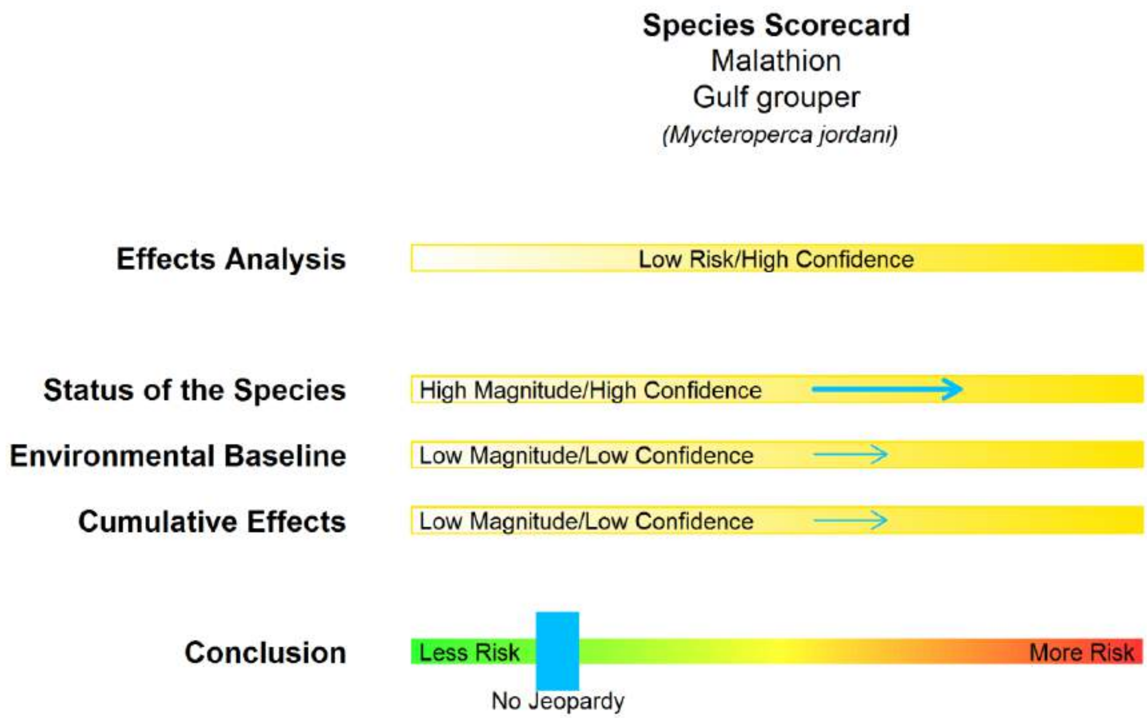

Figure 43. Species Score Card; Gulf grouper; Malathion

Effects Analysis: Low risk/High confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Abundance levels less than 1% of their historical levels
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

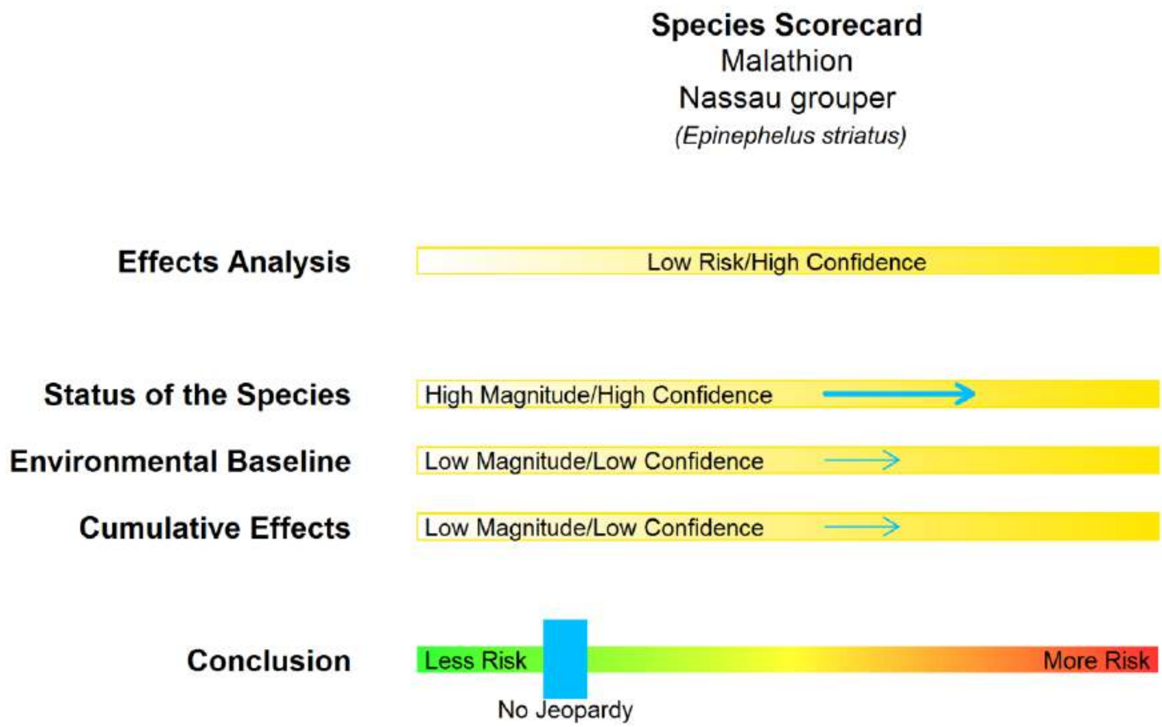

Figure 44. Species Score Card; Nassau grouper; Malathion

<u>Effects Analysis: Low risk/High confidence</u>

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- The species has pathcy abundance with declining abundance trends. Throughout its range reductions in the size and number of spawning aggregations;
- Threatened;
- Recovery criteria not identified

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures not anticipated at toxic concentrations in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures not anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>**Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy**</u>

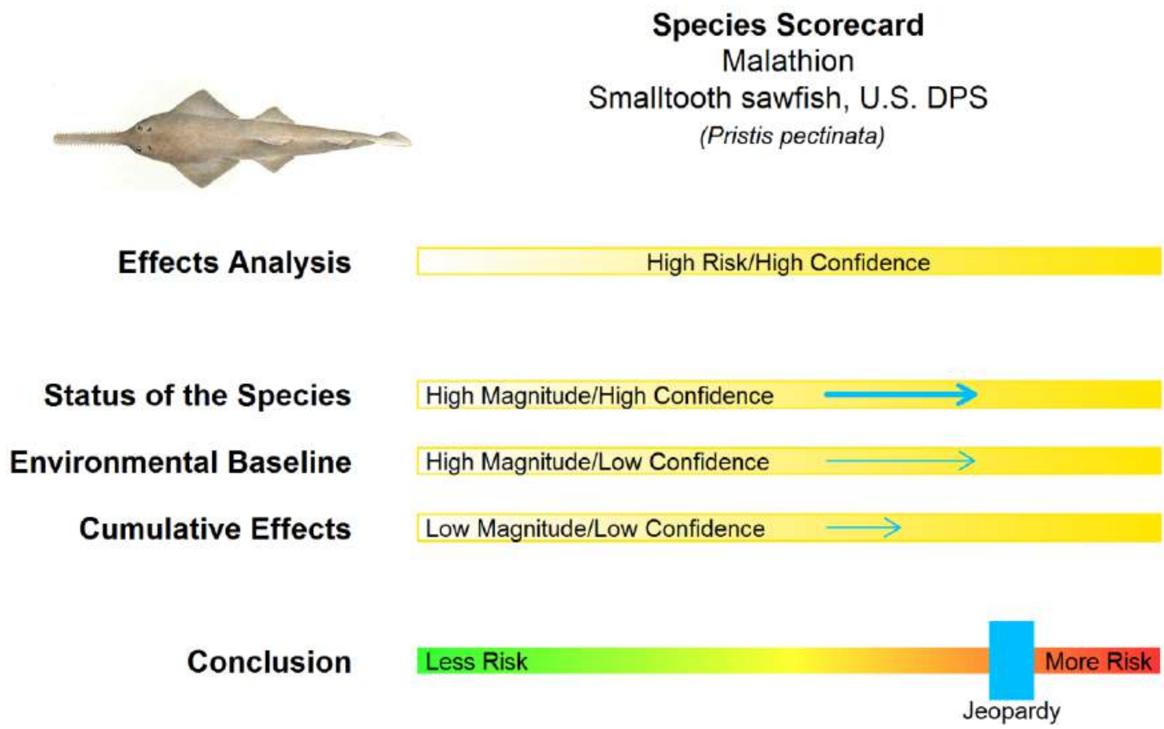

Figure 45. Species Score Card; Smalltooth sawfish, U.S. DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reduced abundance and productivity anticipated in freshwater and estuarine areas
- Anticipated effects include death, reduced cholinesterase activity, reduced growth and prey abundance, impaired swimming, and reduced reproduction.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Stable abundance, low population growth rates, <5% of historical abundance
- Endangered;
- Recovery criteria not met and reduced likelihood of attaining recovery goals

<u>Environmental Baseline: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Elevated temperatures occur in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated
- Anticipated hydrologic effects in freshwater areas

<u>Conclusion:</u> In freshwater habitats, we find a high likelihood of exposure and effects to the species based on high confidence in exposure concentrations. The species is most at risk while in these freshwater areas where they rear, reproduce, and migrate. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action.

<u>**Malathion is likely to jeopardize the continued existence of this species: Jeopardy**</u>

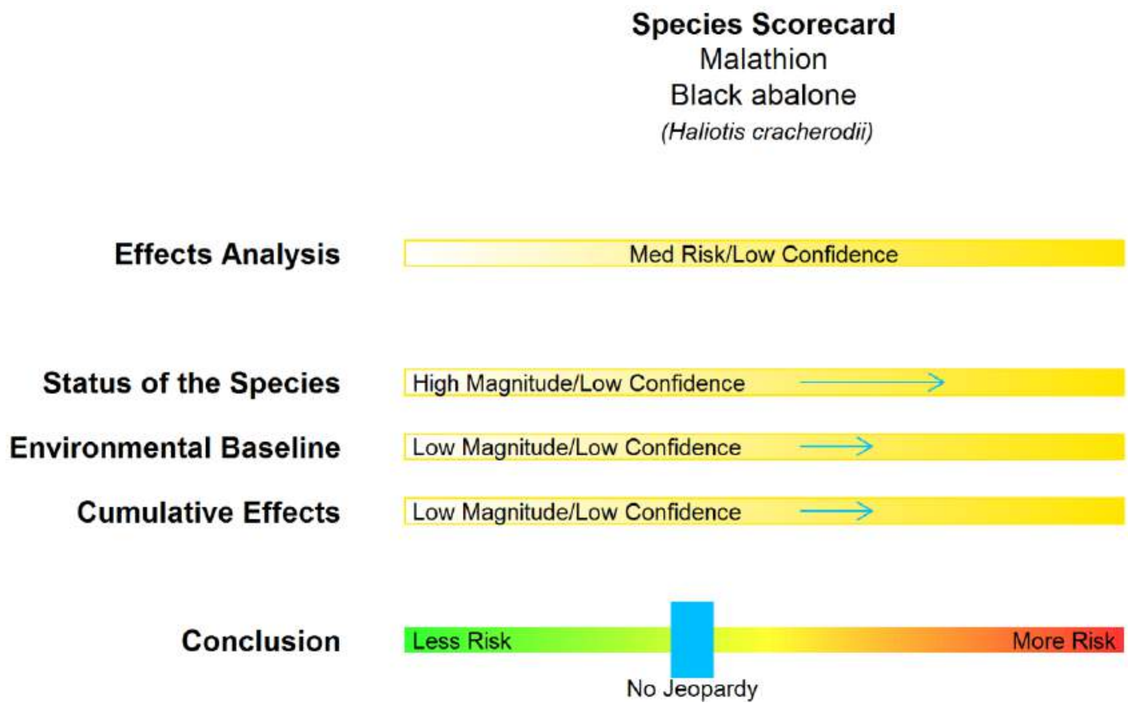

Figure 46. Species Score Card; Black abalone; Malathion

Effects Analysis: Medium risk/Low confidence

- Reduced abundance may occur in marine areas
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- 5% of historical abundance, declining population trend
- Endangered;
- Recovery criteria not identified

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in the surface areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

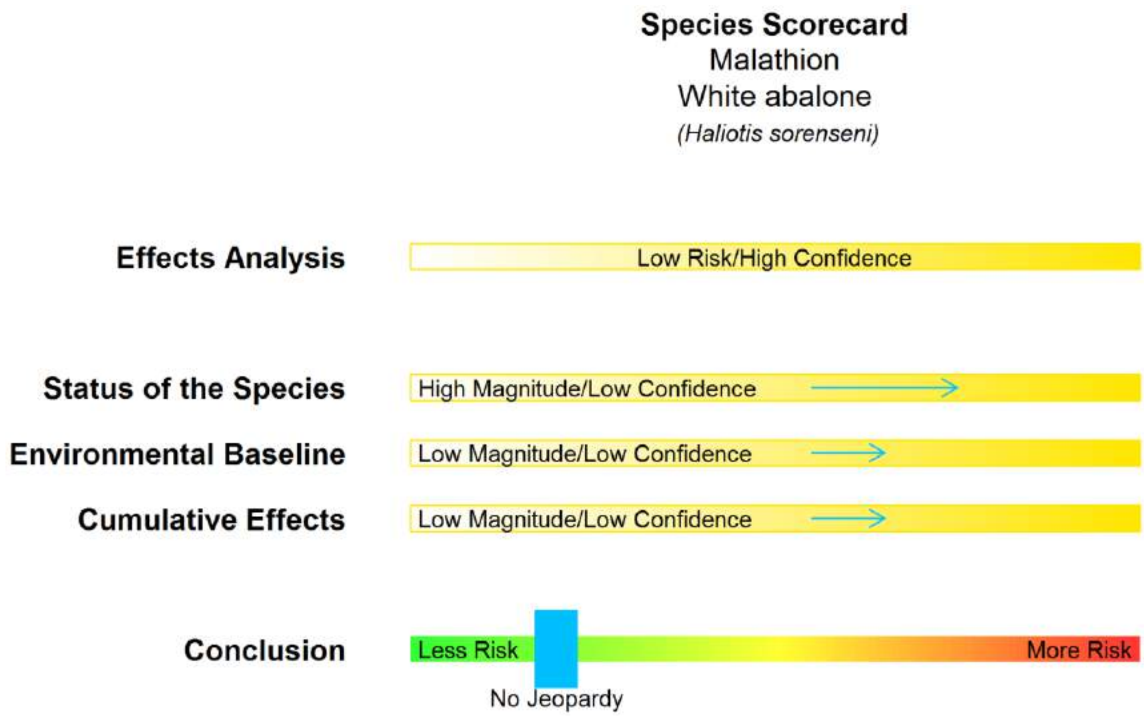

Figure 47. Species Score Card; White abalone; Malathion

Effects Analysis: Low risk/High confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some individual include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Declining population trend, lack of recruitment, no current estimated population size
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures unanticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures not anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on high confidence in minimal exposure to the stressor of the action. The species is most at risk while in the surface areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

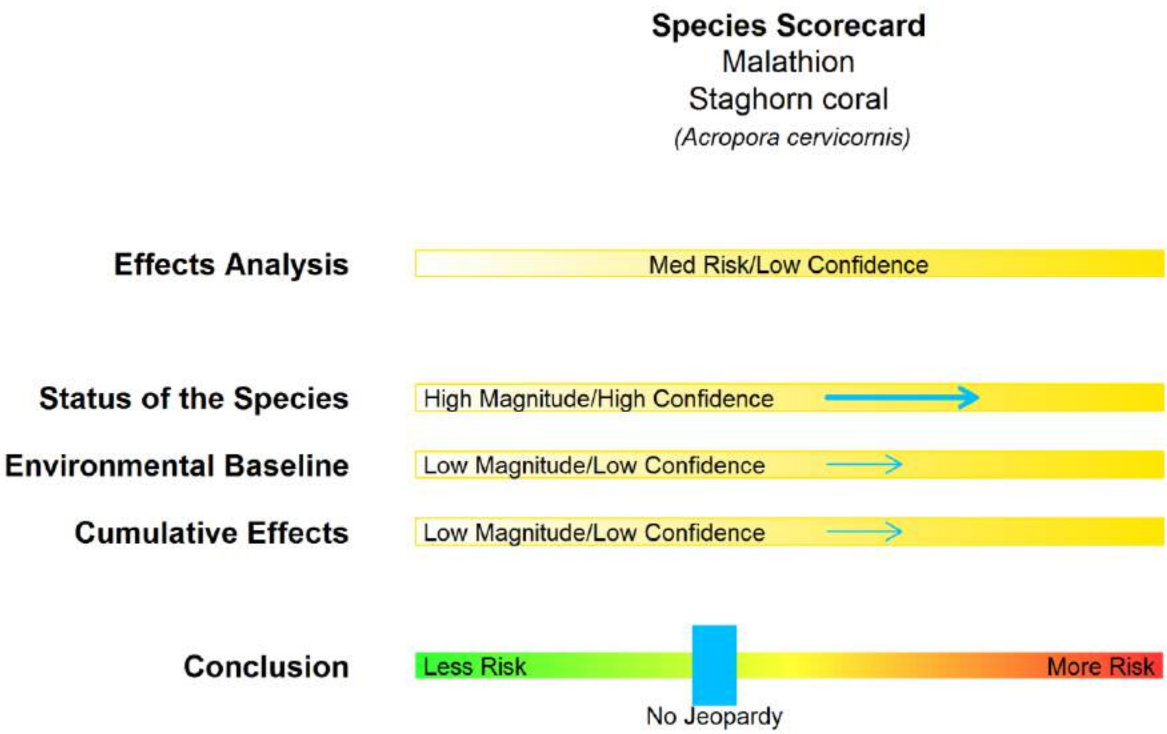

Figure 48. Species Score Card; Staghorn coral; Malathion

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- Severe reductions in abundance in portions of range. Populations remain stable at depressed levels;
- Threatened;
- Recovery criteria not met.

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on high confidence in minimal exposure to the stressor of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

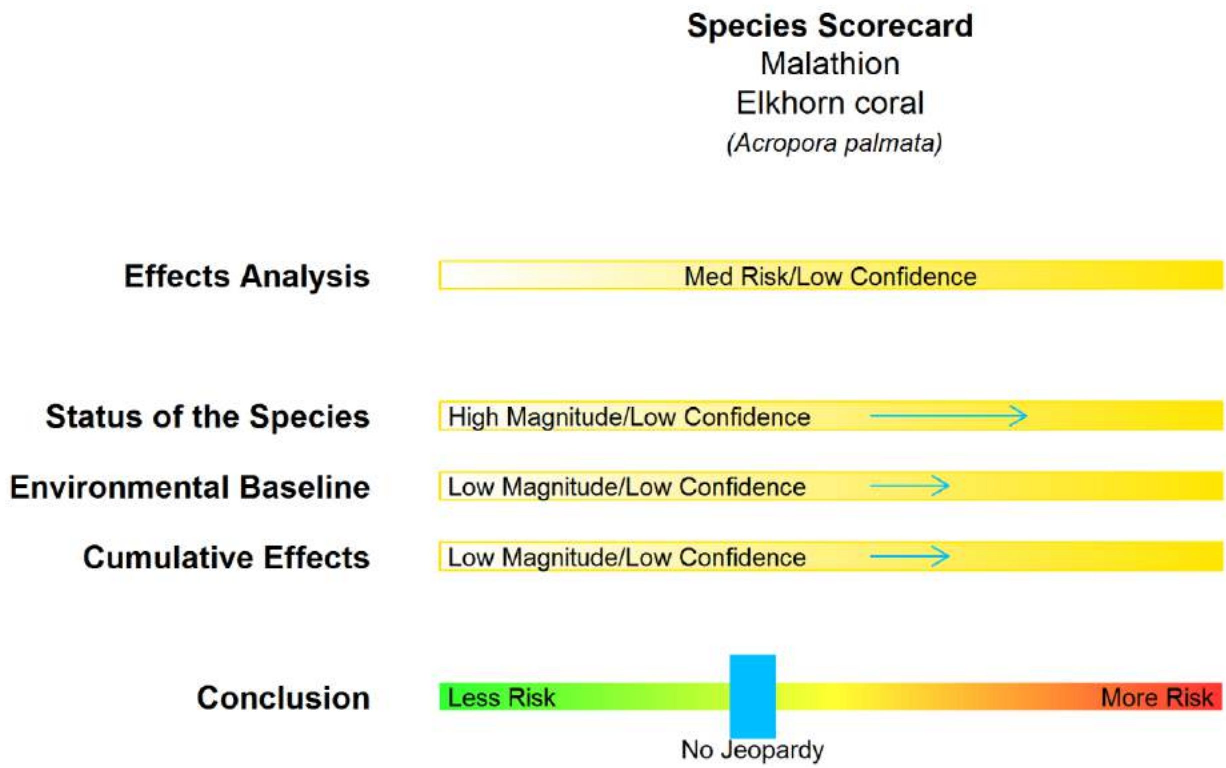

Figure 49. Species Score Card; Elkhorn coral; Malathion

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence</u>

- Low abundance, large declines over past decades. Genetically depauparate populations in Caribbean. In eastern Caribbean, population is doing better and is genetically richer.
- Threatened;
- Recovery criteria not met.

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on high confidence in minimal exposure to the stressor of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>**Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy**</u>

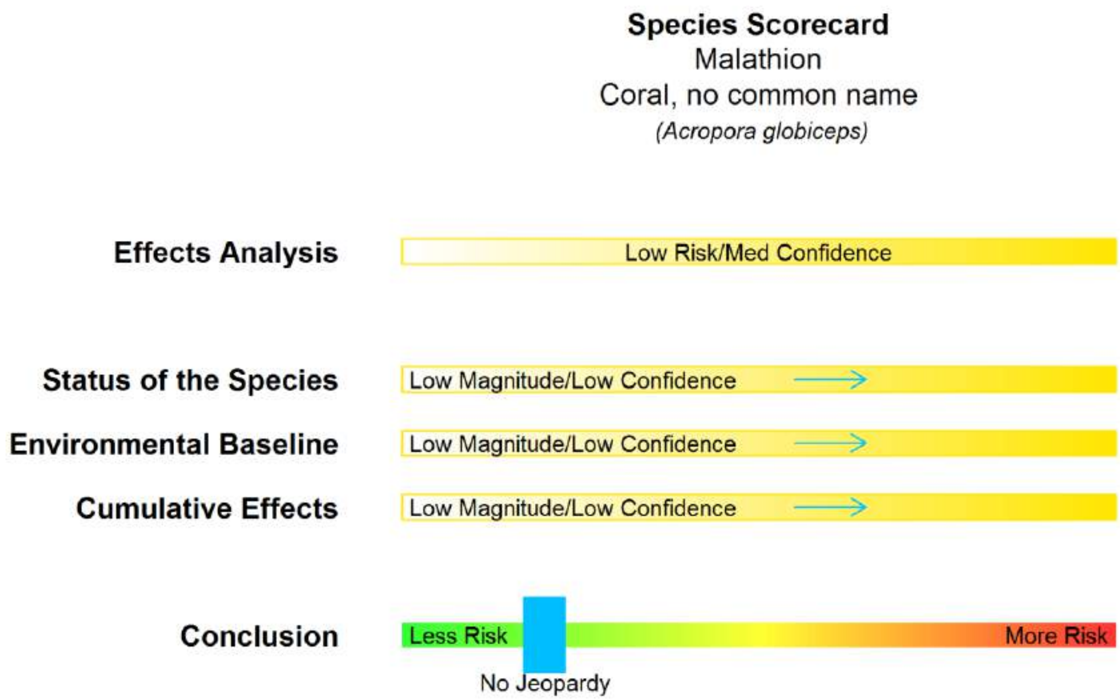

Figure 50. Species Score Card; Coral, Acropora globiceps; Malathion

<u>Effects Analysis: Low risk/Medium confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

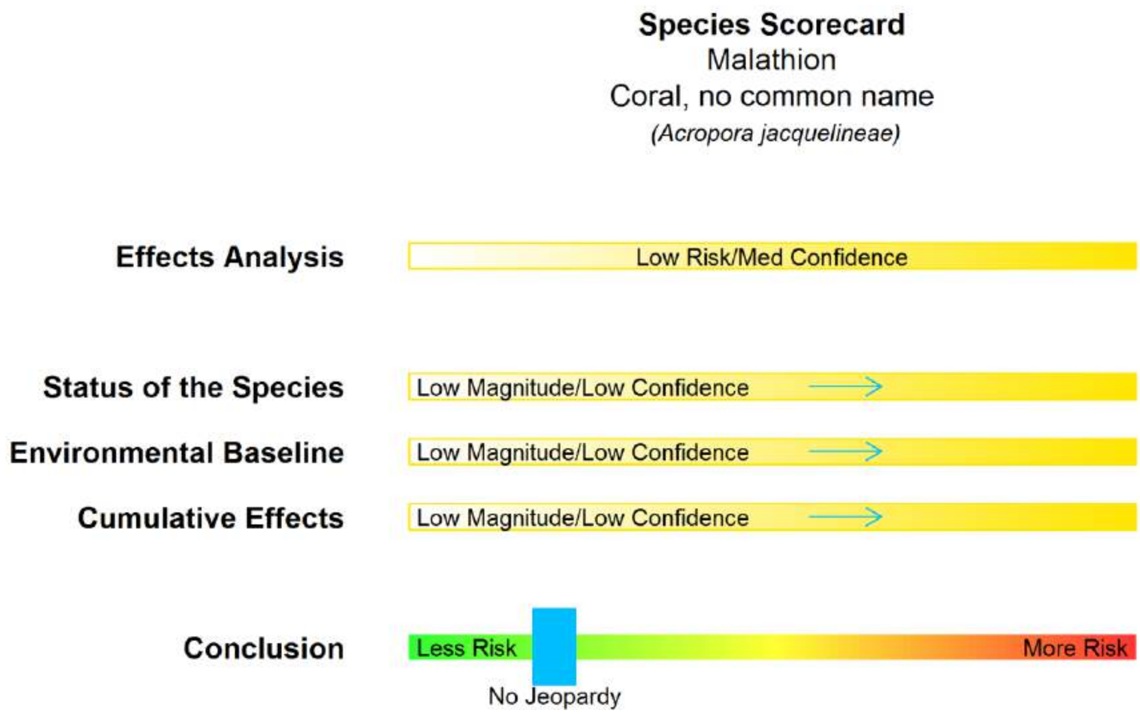

Figure 51. Species Score Card; Coral, Acropora jacquelineae; Malathion

<u>Effects Analysis: Low risk/Medium confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

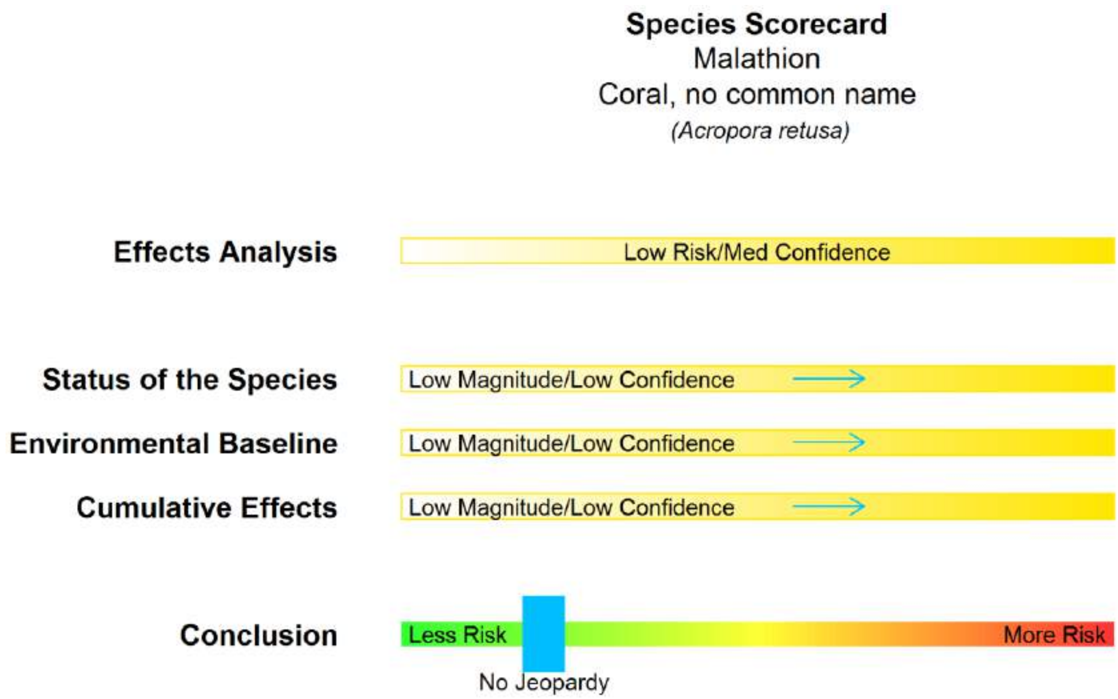

Figure 52. Species Score Card; Coral, Acropora retusa; Malathion

Effects Analysis: Low risk/Medium confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

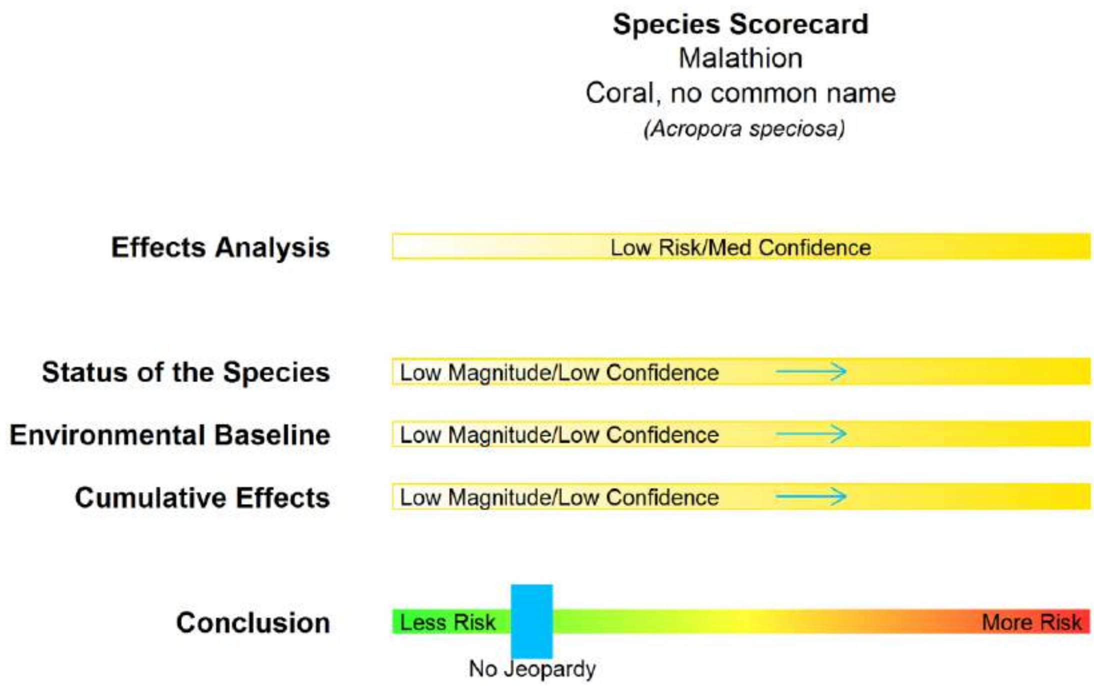

Figure 53. Species Score Card; Coral, Acropora speciosa; Malathion

Effects Analysis: Low risk/Medium confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

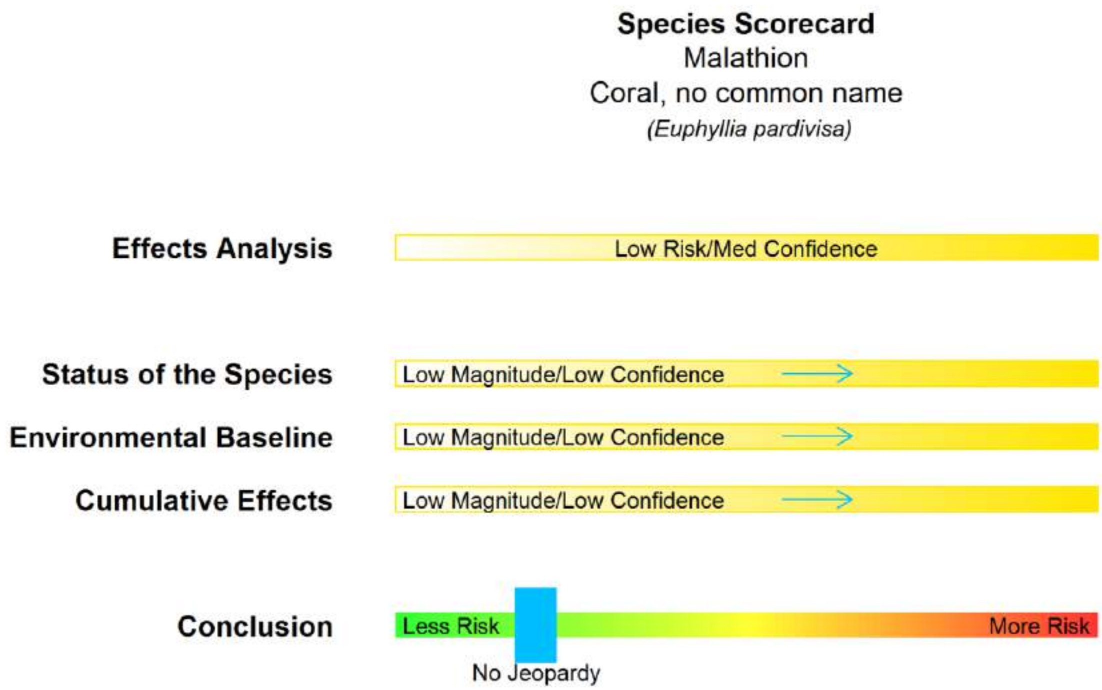

Figure 54. Species Score Card; Coral, Euphyllia pardivisa; Malathion

<u>Effects Analysis: Low risk/Medium confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

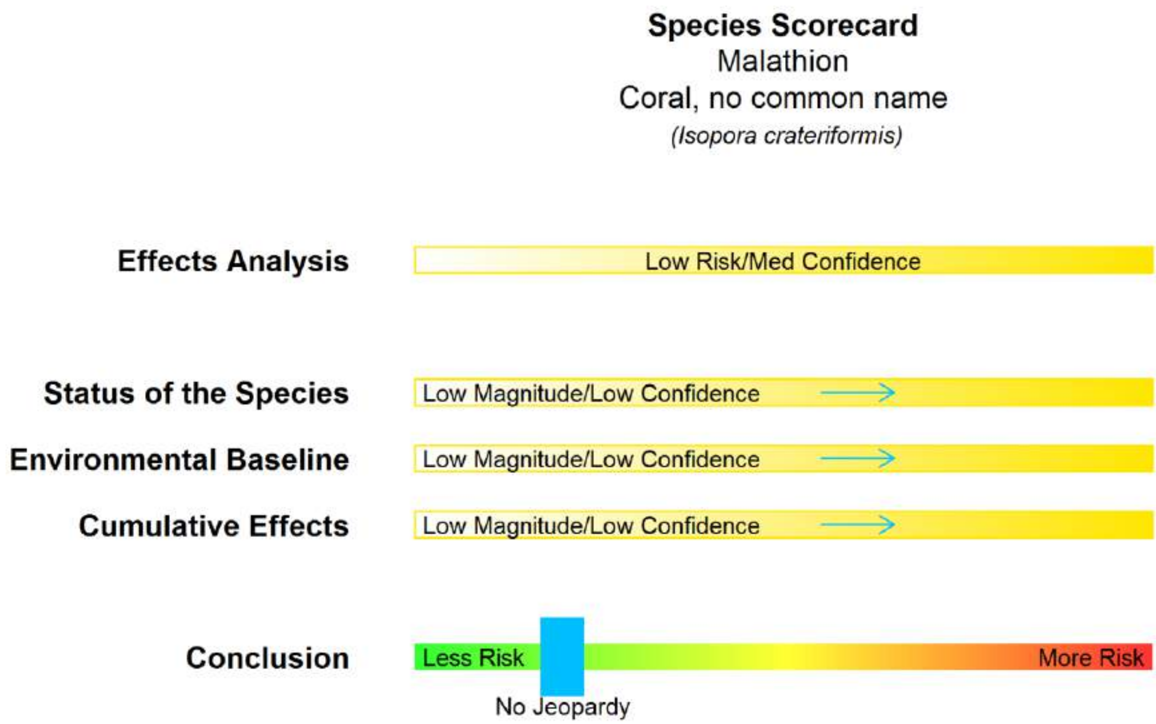

Figure 55. Species Score Card; Coral, Isopora crateriformis; Malathion

Effects Analysis: Low risk/Medium confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

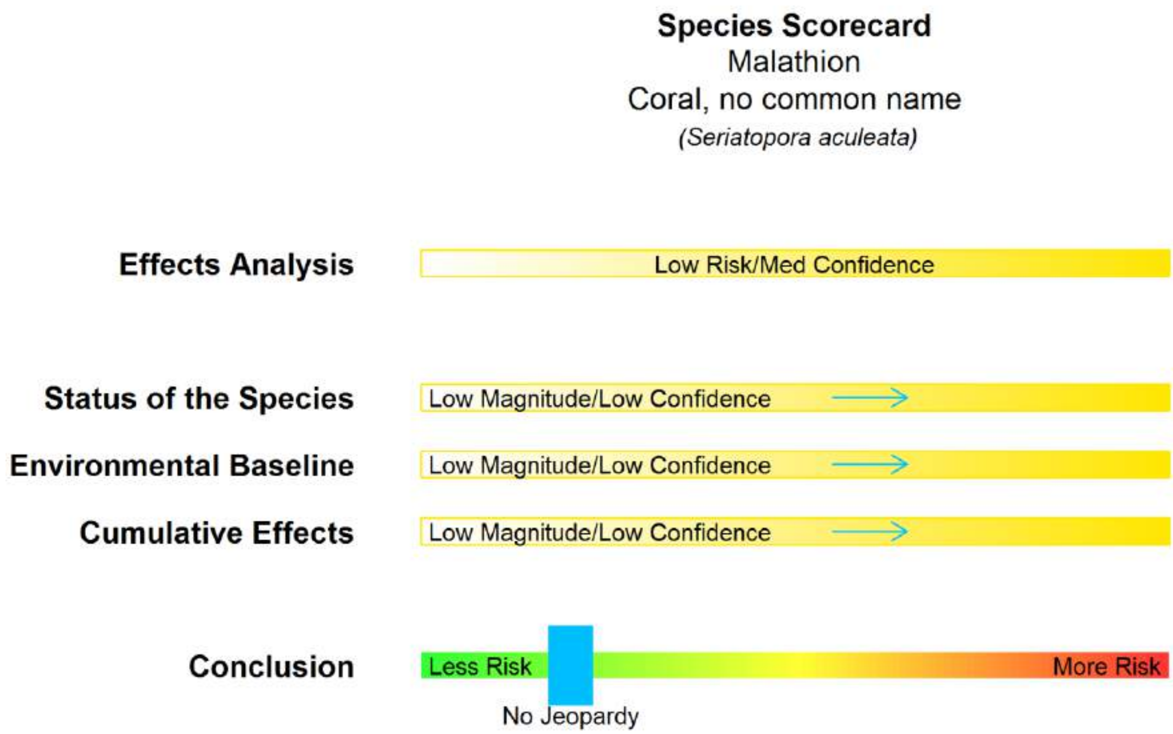

Figure 56. Species Score Card; Coral, Seriatopora aculeata; Malathion

<u>Effects Analysis: Low risk/Medium confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to colonies include death and reduced settling of juveniles.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Range is extensive throughout the Indo-Pacific region. Less than 5 % of the population is within the range of the action area. Over-all status unknown. Growth rates of decline or increase are unknown.
- Threatened;
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

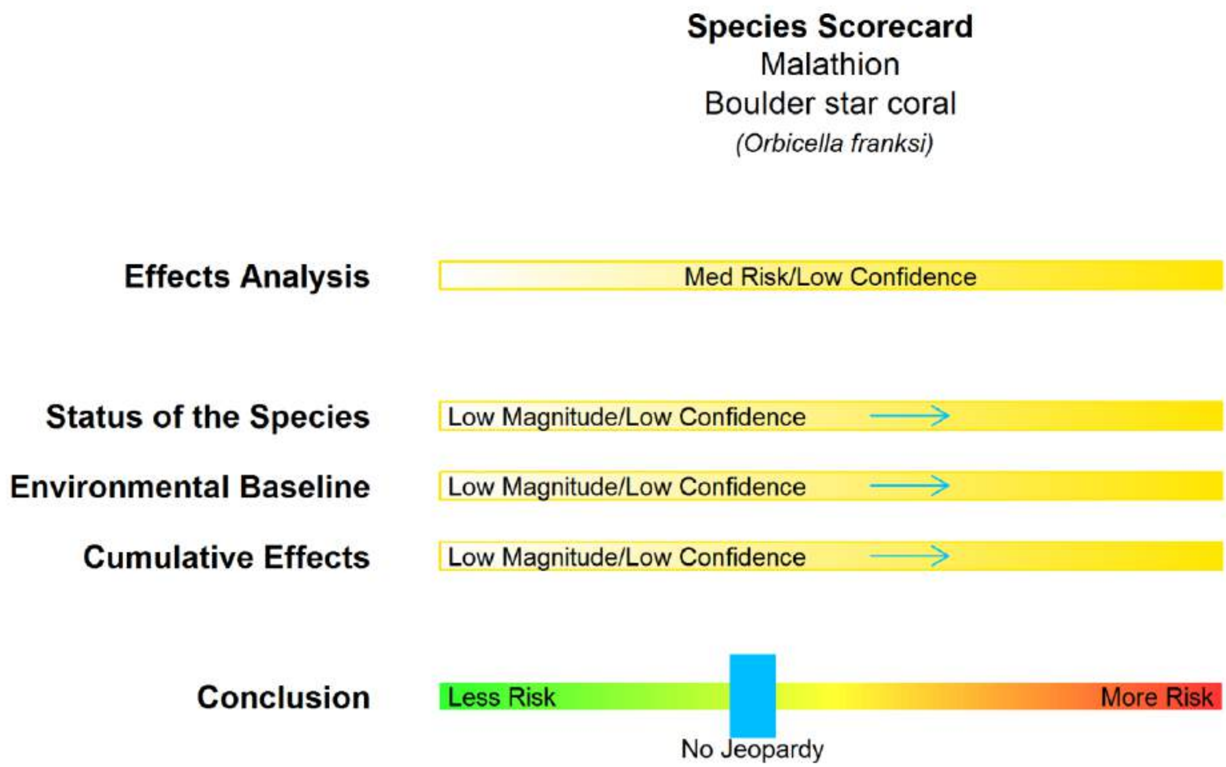

Figure 57. Species Score Card; Boulder star coral; Malathion

Effects Analysis: Medium risk/Low confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Reductions in abundance, population is currently stable
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 5% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

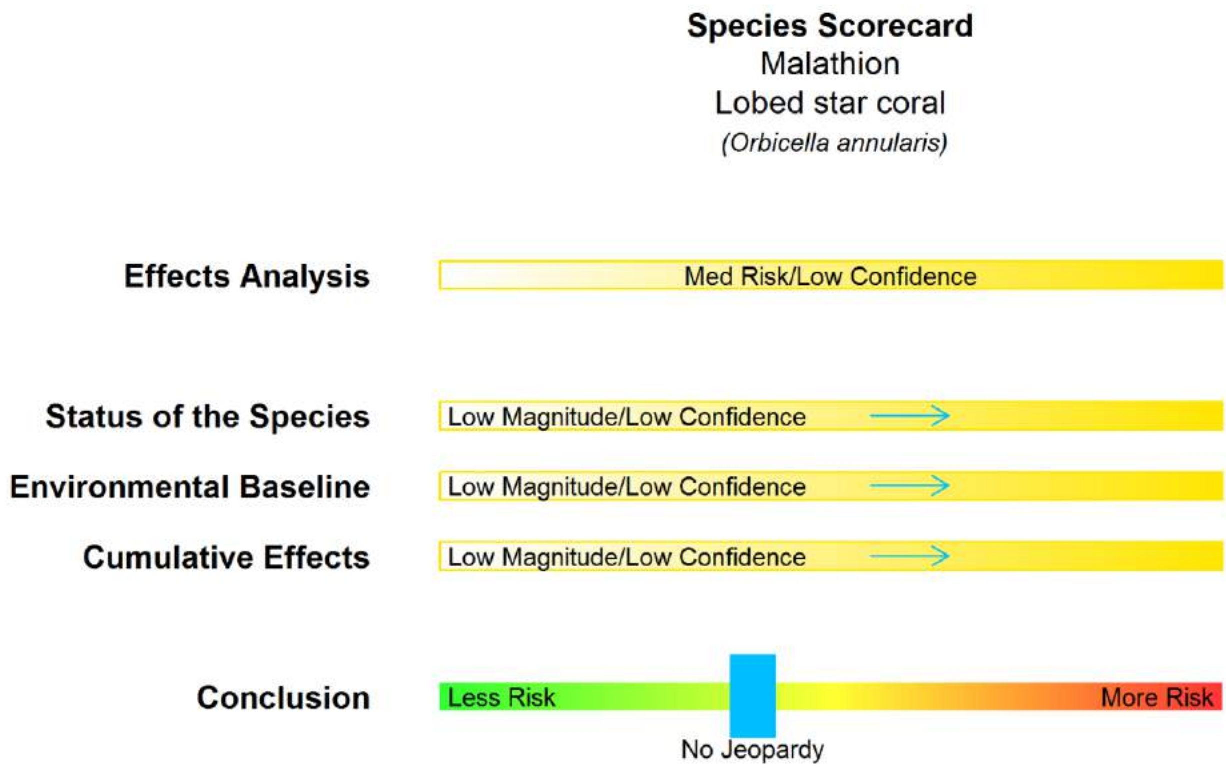

Figure 58. Species Score Card; Lobed star coral; Malathion

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- 60% decline 2001-2012 due to bleaching. Most were considered "partial" mortalities to the colony. Abundance is stable.
- Threatened;
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 8% of the species’ range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species’ numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

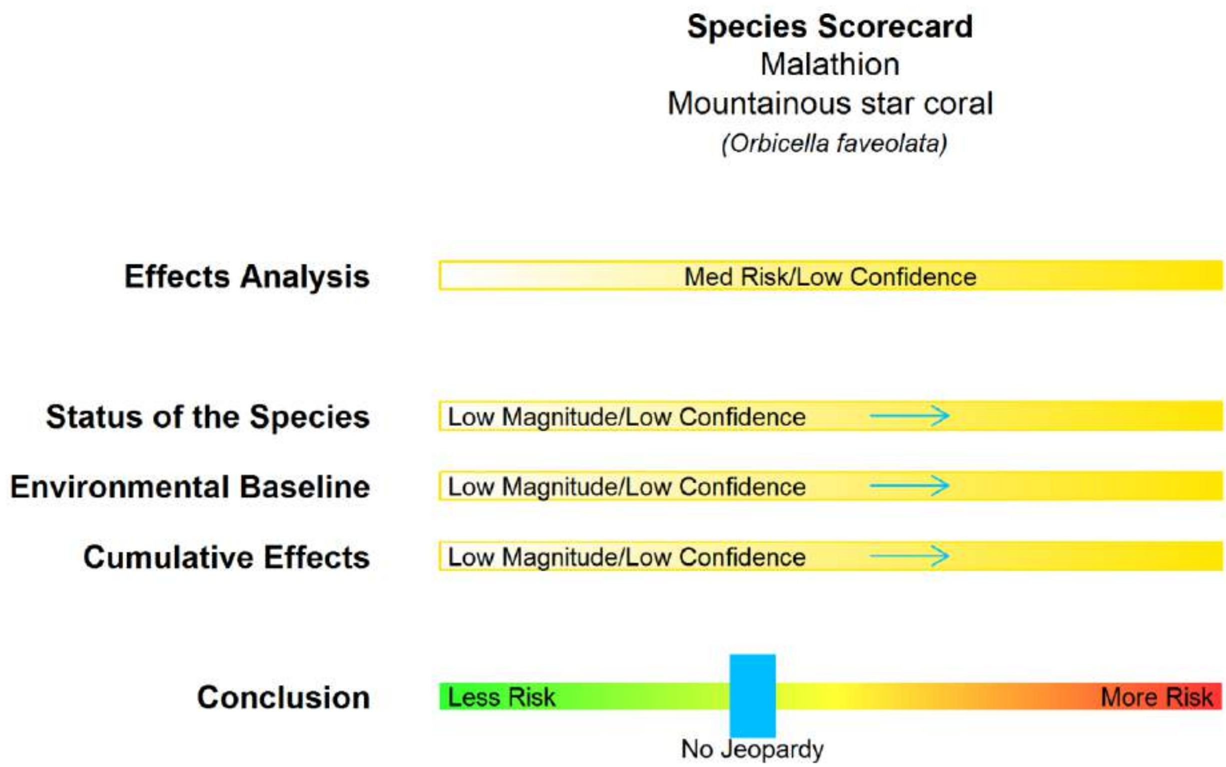

Figure 59. Species Score Card; Mountainous star coral; Malathion

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Some areas have shown major declines due to warming induced bleaching and disease; however this species is considered abundant.
- Threatened;
- Recovery criteria not developed

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

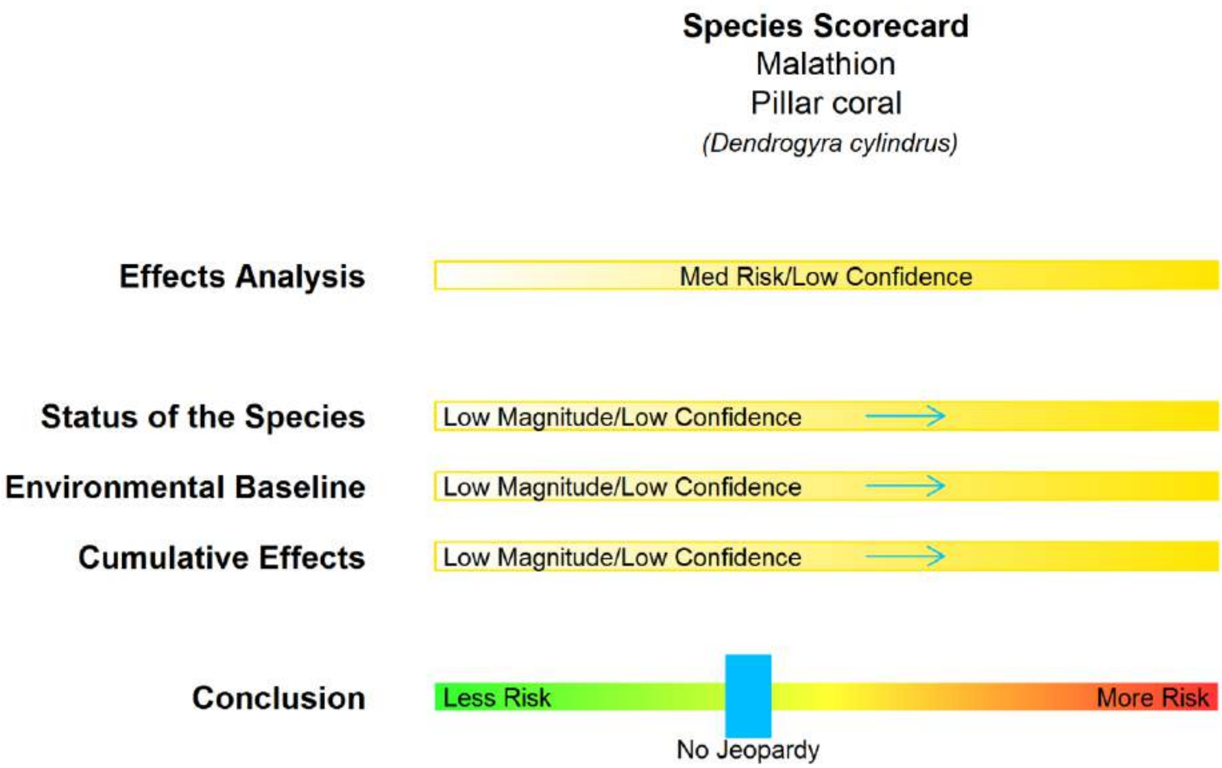

Figure 60. Species Score Card; Pillar coral; Malathion

Effects Analysis: Medium risk/Low confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Uncommon, rarely found in aggregations - yet little evidence of population declines over years of monitoring. Unknown trends in abundance or productivity
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

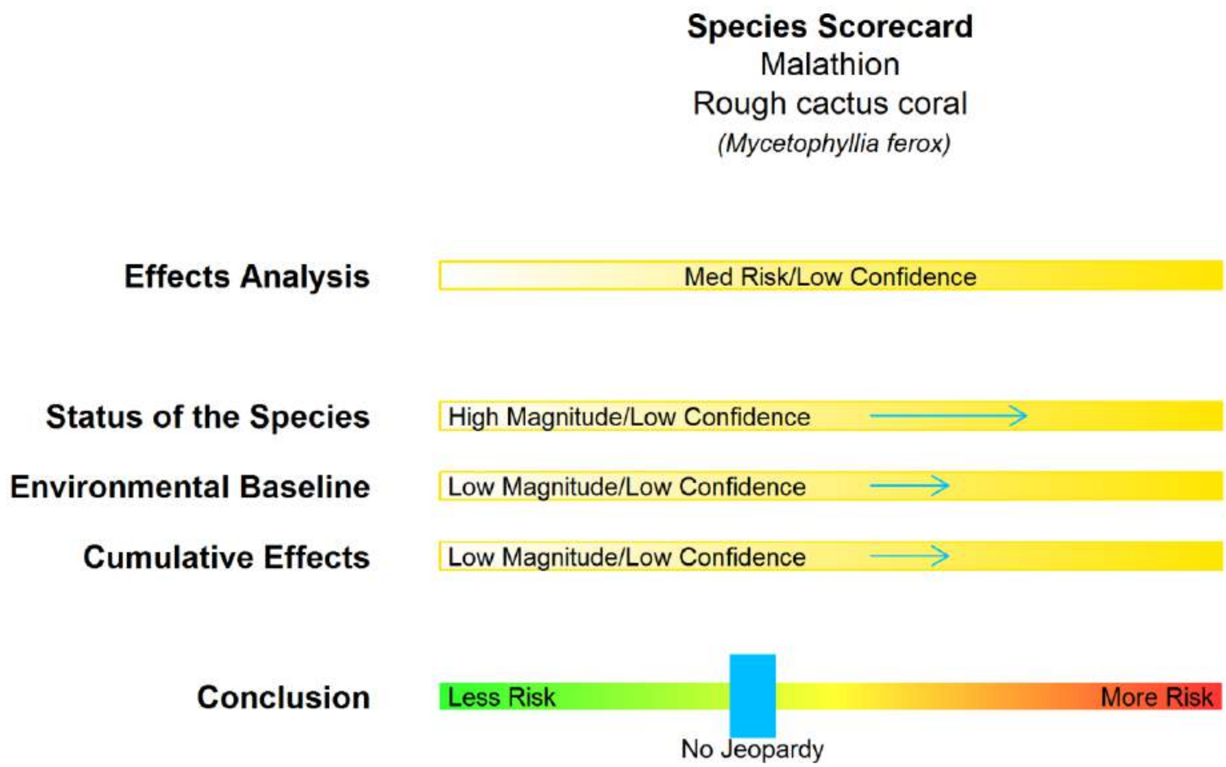

Figure 61. Species Score Card; Rough cactus coral; Malathion

Effects Analysis: Medium risk/Low confidence

- Reduced abundance unlikely to occur in marine areas
- Potential effects to some colonies include death and reduced settling of juveniles.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Uncommon to rare. Species saw declines since the 1970's. Highly affected by disease. Unknown trends in abundance or productivity
- Threatened;
- Recovery criteria not developed

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures anticipated in marine waters
- Environmental mixtures not anticipated to reach toxic concentration in marine habitats

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on medium confidence in minimal exposure to the stressors of the action. Additionally, a maximum of 8% of the species' range is in U.S. jurisdiction. The species is most at risk where colonies are proximate to river and stream mouths. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

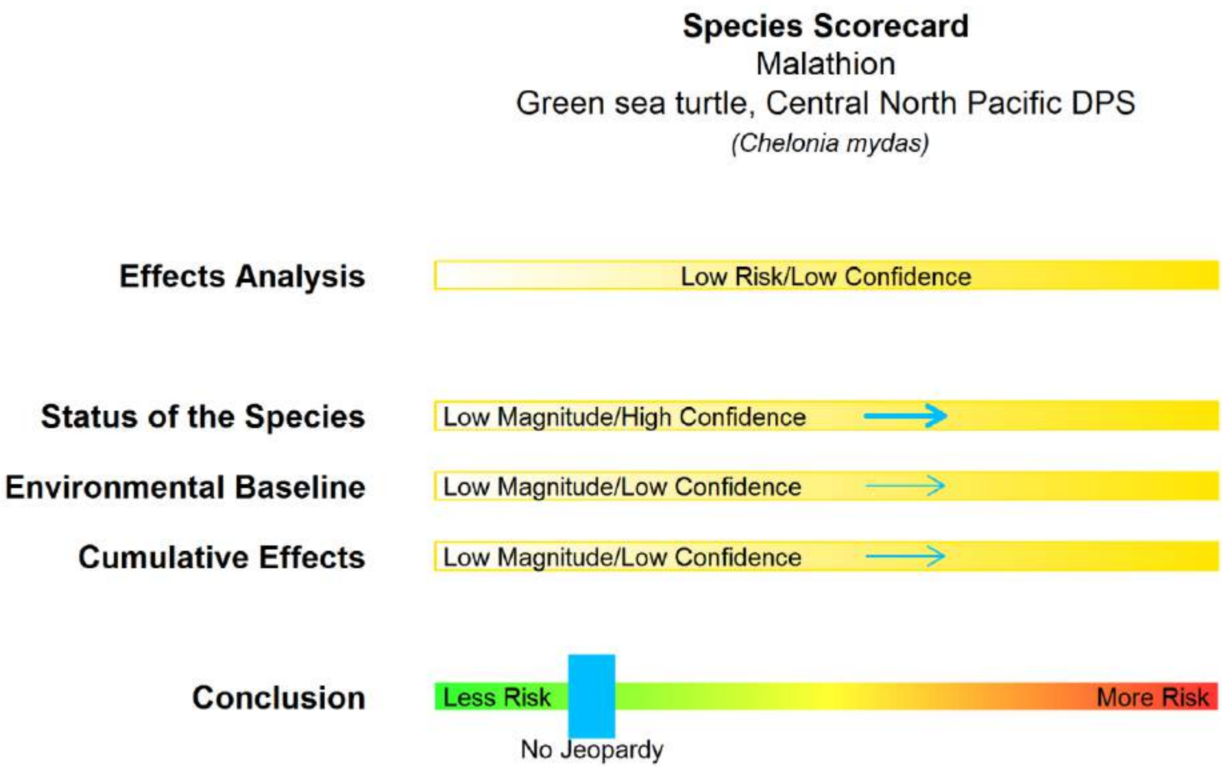

Figure 62. Species Score Card; Green sea turtle, Central North Pacific DPS; Malathion

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects may include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- Population nesting abundance is increasing at estimated rate of 4.8% annually. DPS has low level of genetic diversity. Population considered resilient.
- Threatened;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

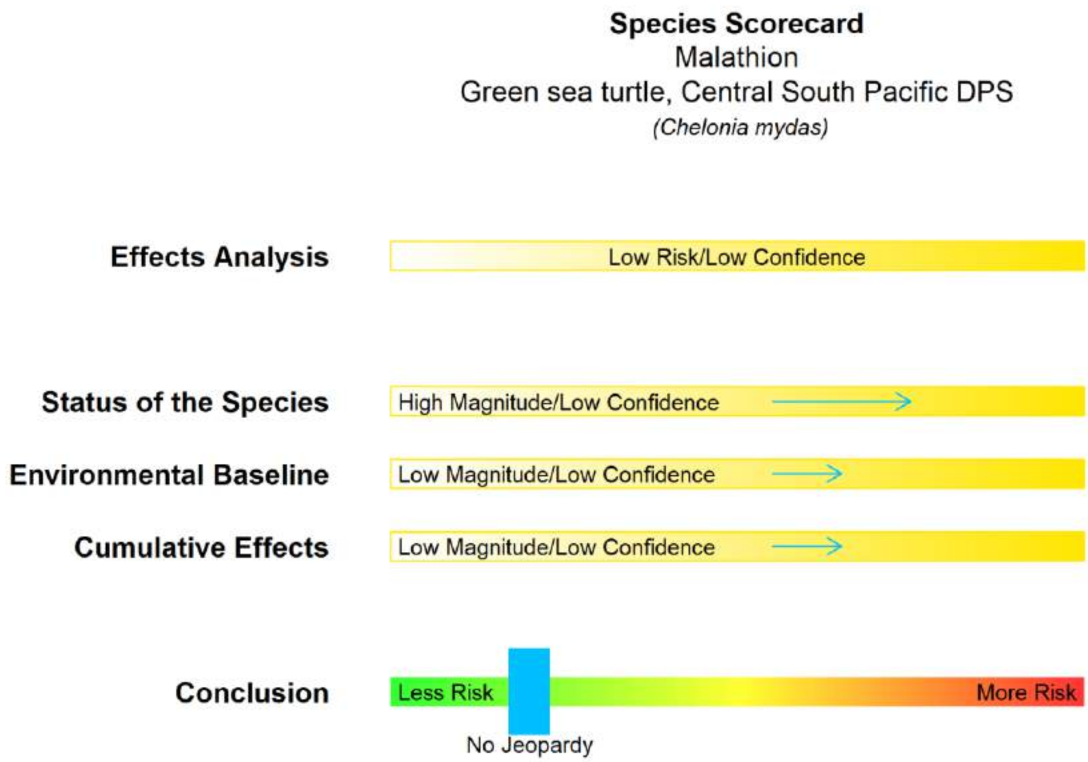

Figure 63. Species Score Card; Green sea turtle, Central South Pacific DPS; Malathion

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects may include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- Nesting abundance considered low, 59 known sites; Unknown population trends; Existing data suggest steep declines due to illegal harvest of eggs. Nesting areas typically outside of the action area (US, territories, protectorates, etc.)
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

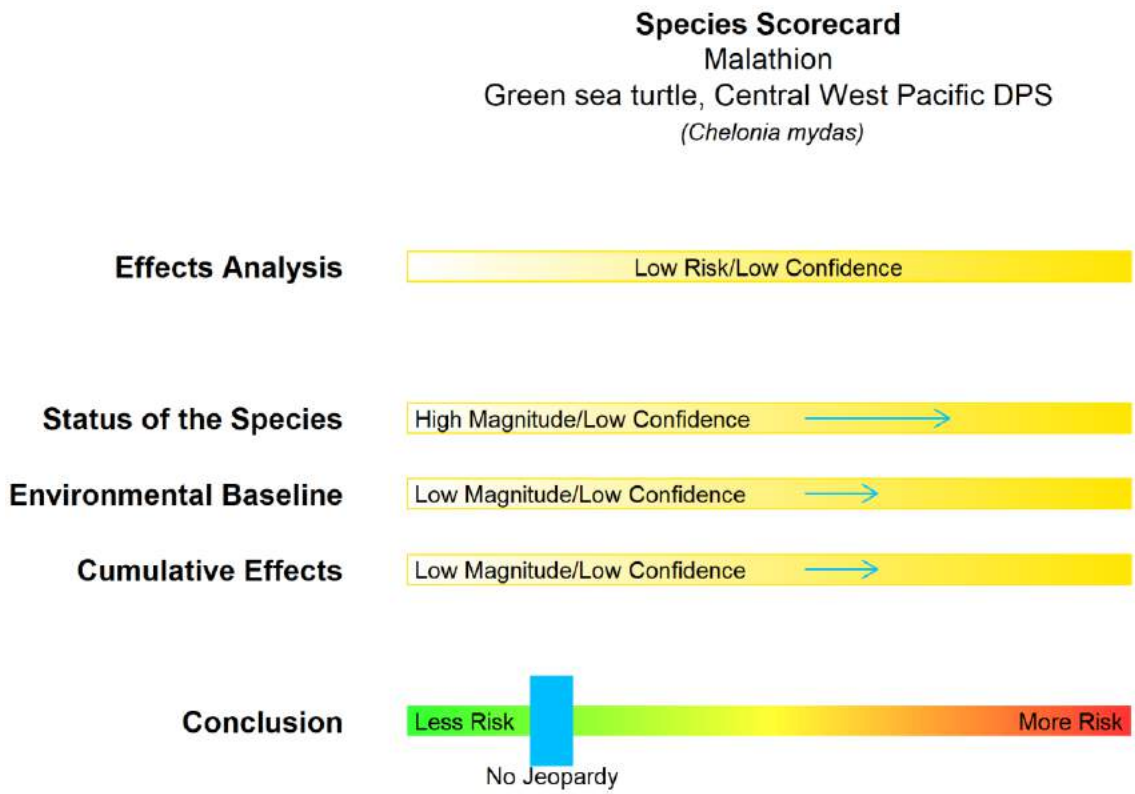

Figure 64. Species Score Card; Green sea turtle, Central West Pacific DPS; Malathion

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects may include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ Low confidence

- No available population trend data; Most of species' range outside of action area.
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

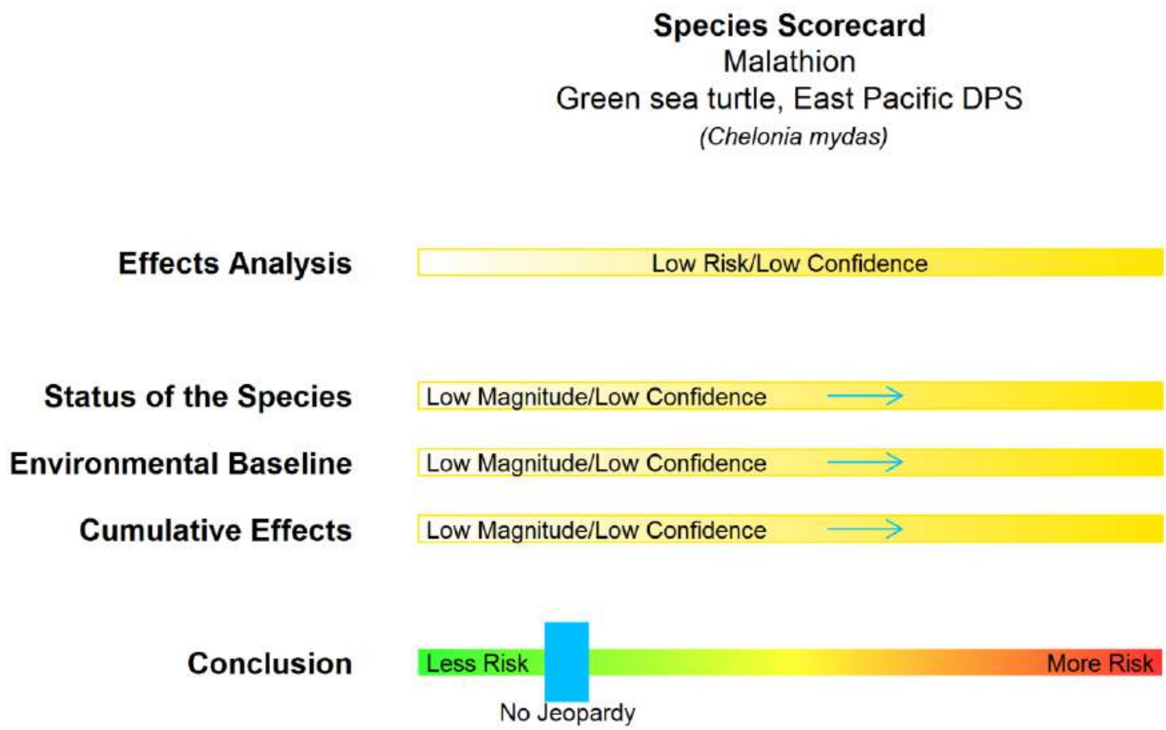

Figure 65. Species Score Card; Green sea turtle, East Pacific DPS; Malathion

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects may include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- 39 nesting sites with an estimated 20,062 nesting females.; The largest nesting site is at Colola, Mexico, which hosts 58% of the nesting females for the DPS where monitoring data suggest the population is increasing.
- Threatened;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

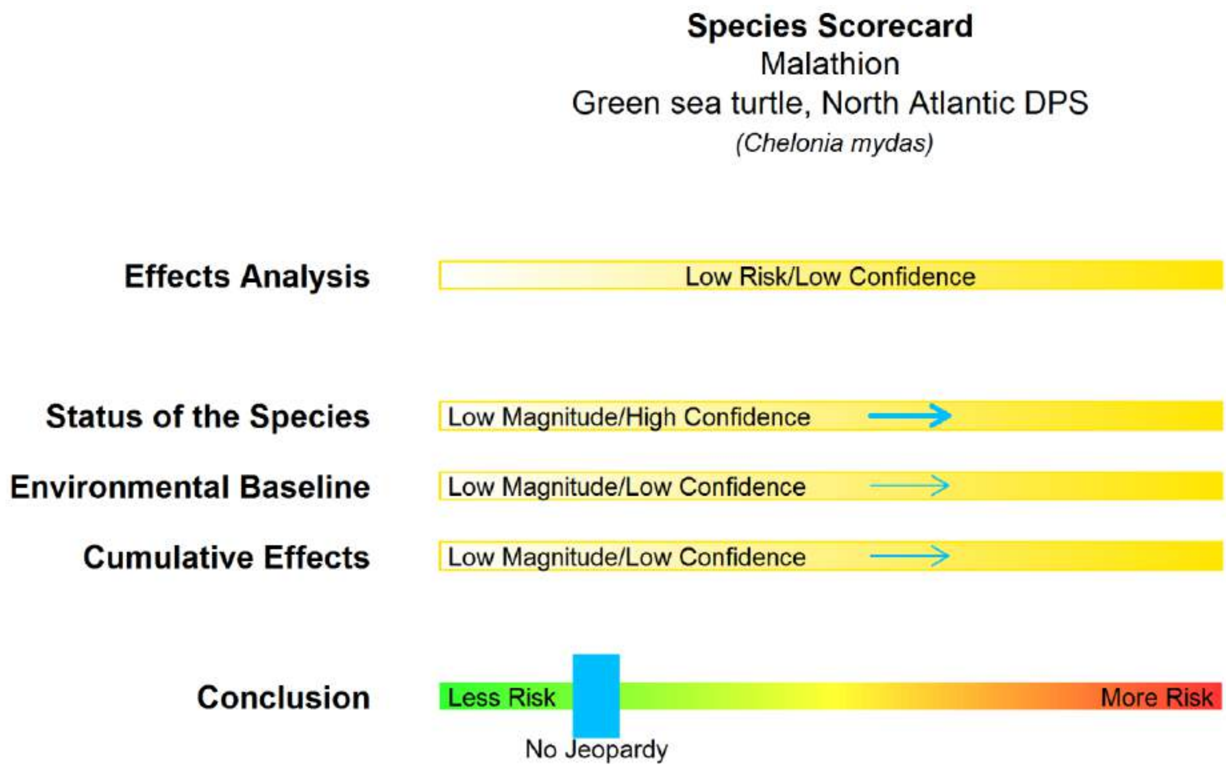

Figure 66. Species Score Card; Green sea turtle, North Atlantic DPS; Malathion

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects may include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence

- Population shows increasing trend.
- Threatened;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

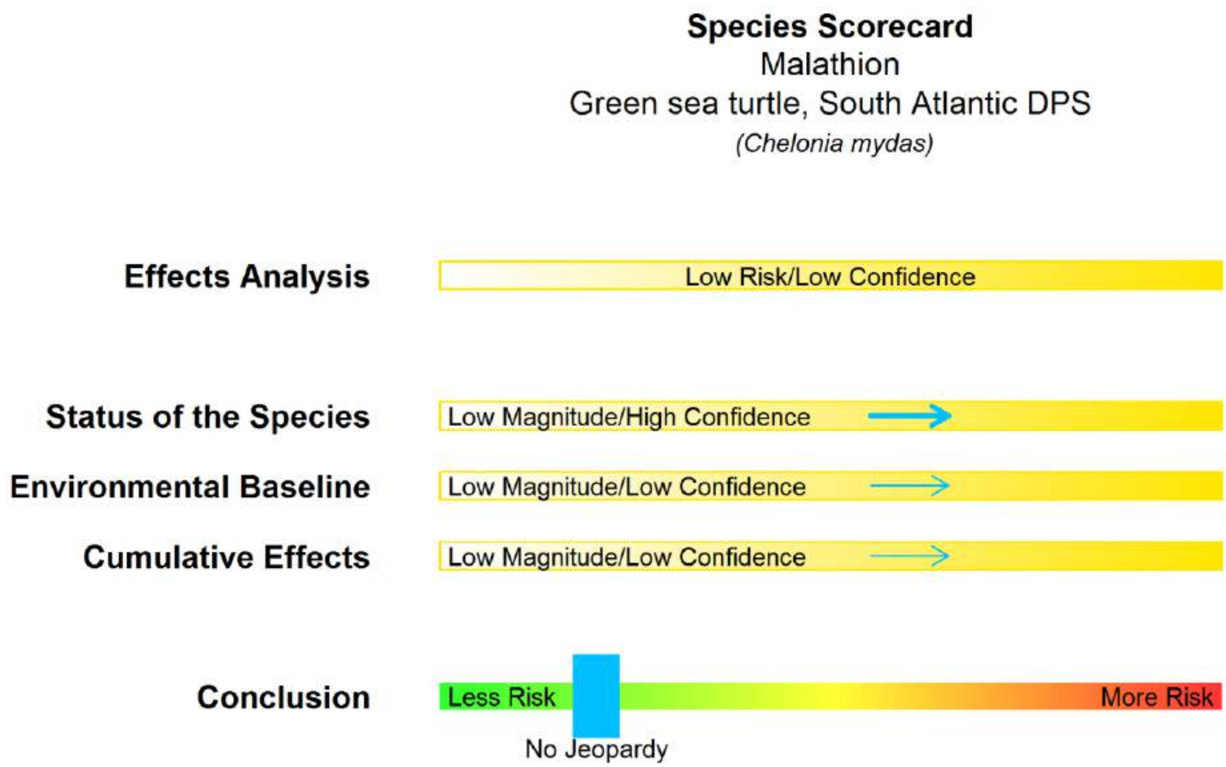

Figure 67. Species Score Card; Green sea turtle, South Atlantic DPS; Malathion

<u>Effects Analysis: Low risk/Low confidence</u>

- Reduced abundance not anticipated
- Potential effects may include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ High confidence</u>

- Sparse data available, suggests population is increasing; Most of DPS range outside of the action area;
- Threatened;
- Recovery criteria not all met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in freshwater habitats that affect species

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>**Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy**</u>

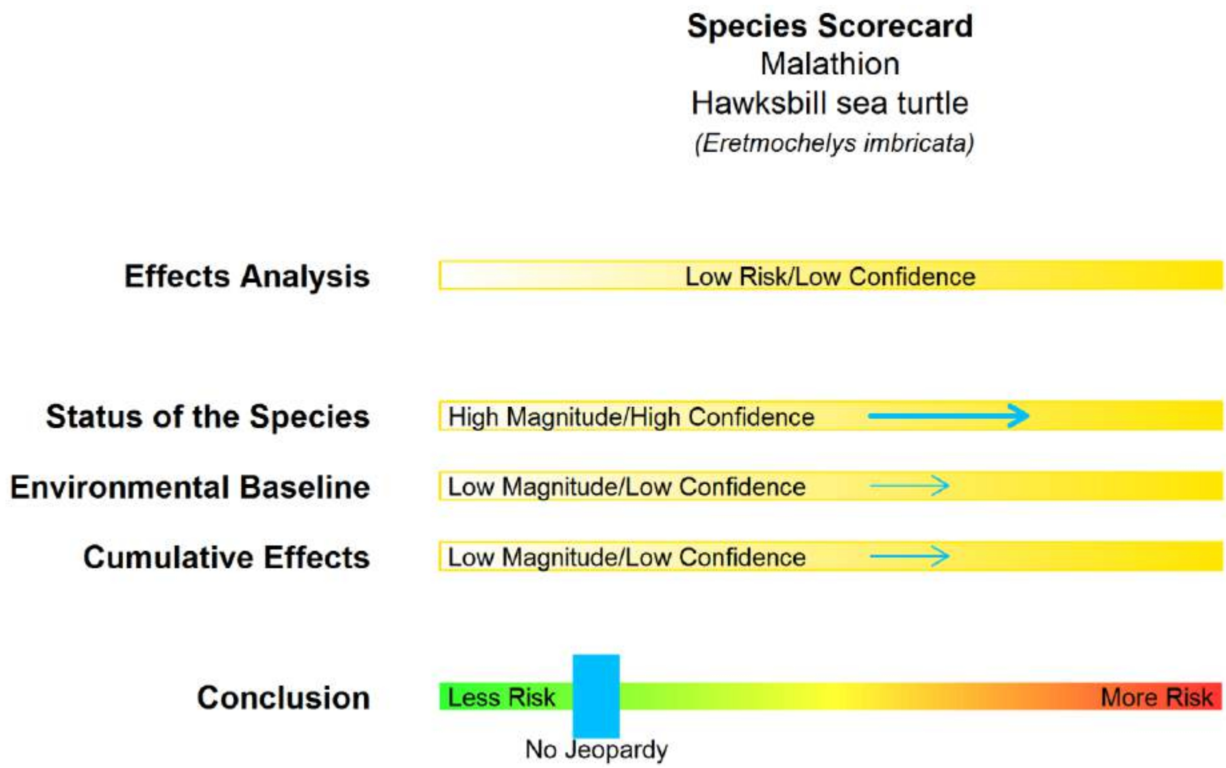

Figure 68. Species Score Card; Hawksbill sea turtle; Malathion

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Population abundance improving in Atlantic and Indian Ocean; abundance declining in Pacific Ocean over the last 20 - 100 years. 68% of nesting sites exhibited declines.
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

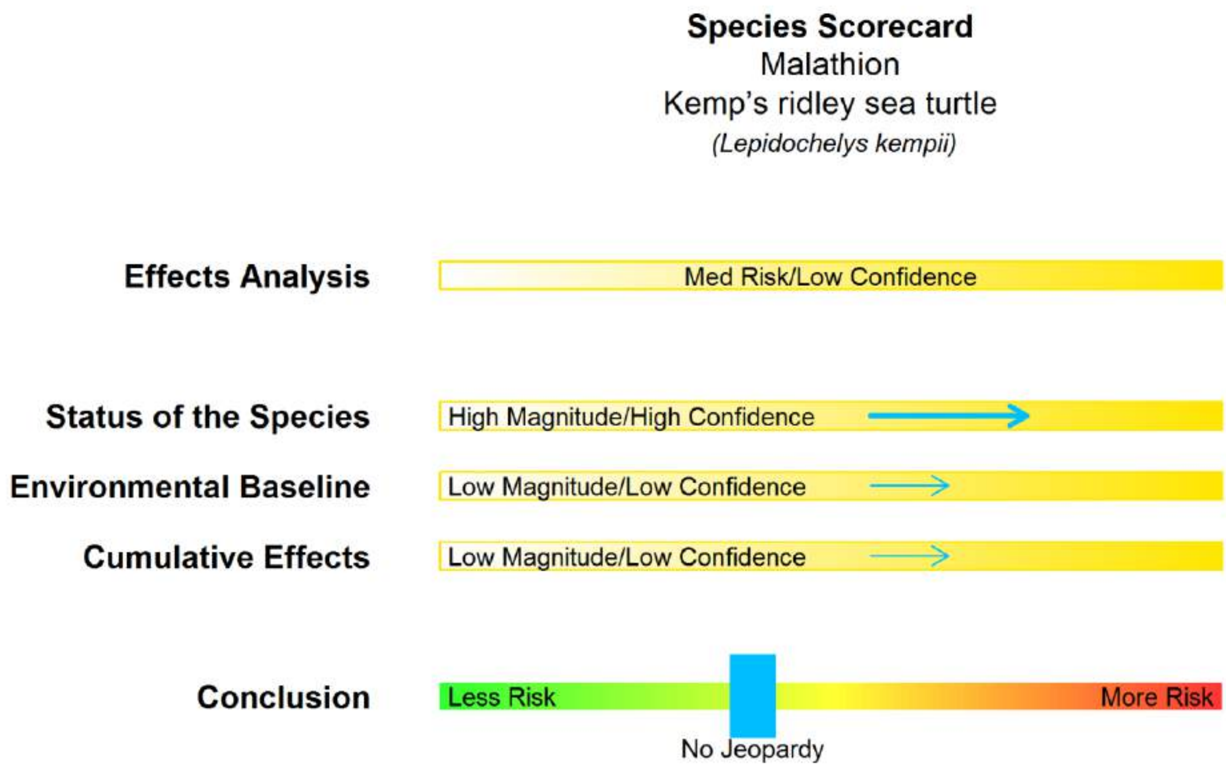

Figure 69. Species Score Card; Kemp's ridley sea turtle; Malathion

Effects Analysis: Medium risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; High magnitude/ High confidence

- Abundance trends negative;
- Endangered;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

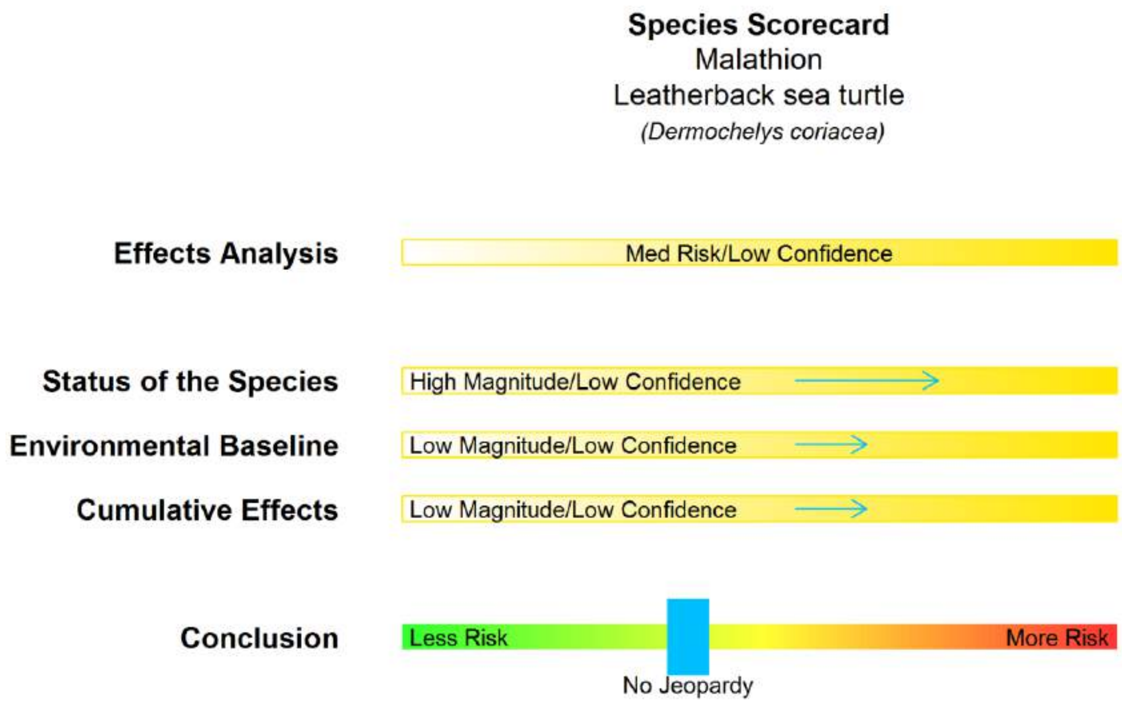

Figure 70. Species Score Card; Leatherback sea turtle; Malathion

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Minimal increased risk of jeopardy; High magnitude/ Low confidence</u>

- Pacific population declined from 81,000 in to less than 3,000 with a continued rate of loss of approximately 6 %. Atlantic population is stable and showing signs of increasing growth of between 4-5.6% and 9-13% in Florida and the U.S. Virgin Islands, respectively.
- Endangered;
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

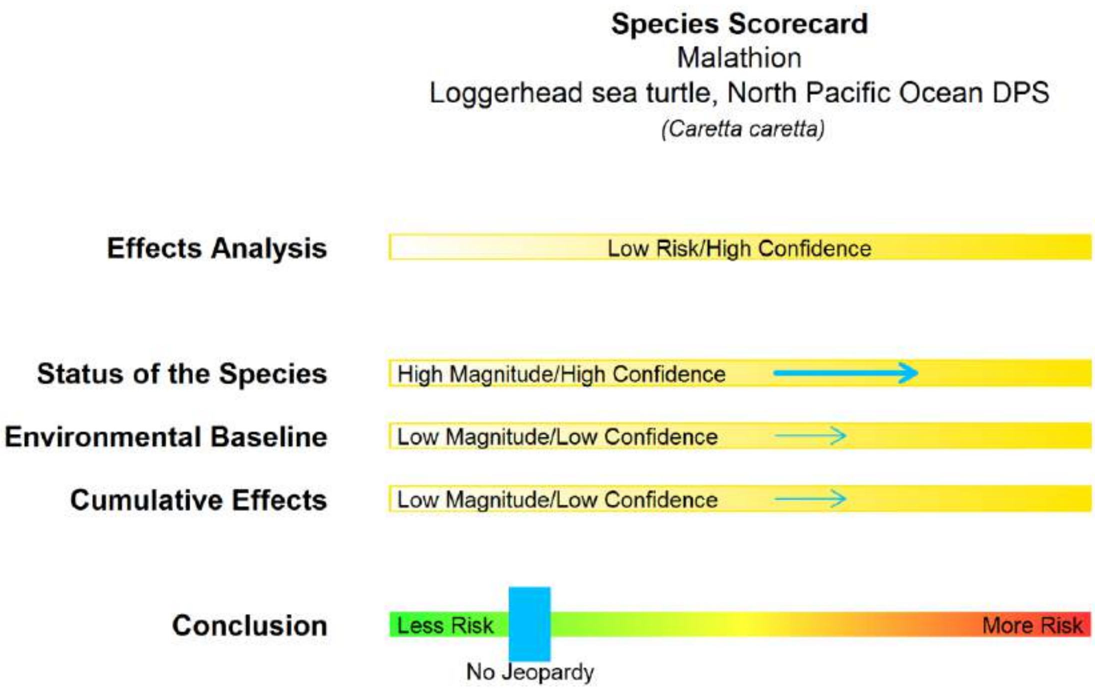

Figure 71. Species Score Card; Loggerhead sea turtle, North Pacific Ocean DPS; Malathion

Effects Analysis: Low risk/High confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Population growth rate estimated at 0.032. Population depressed compared to historical numbers.
- Threatened; Population has declined an estimated 80% in past 20 years.
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

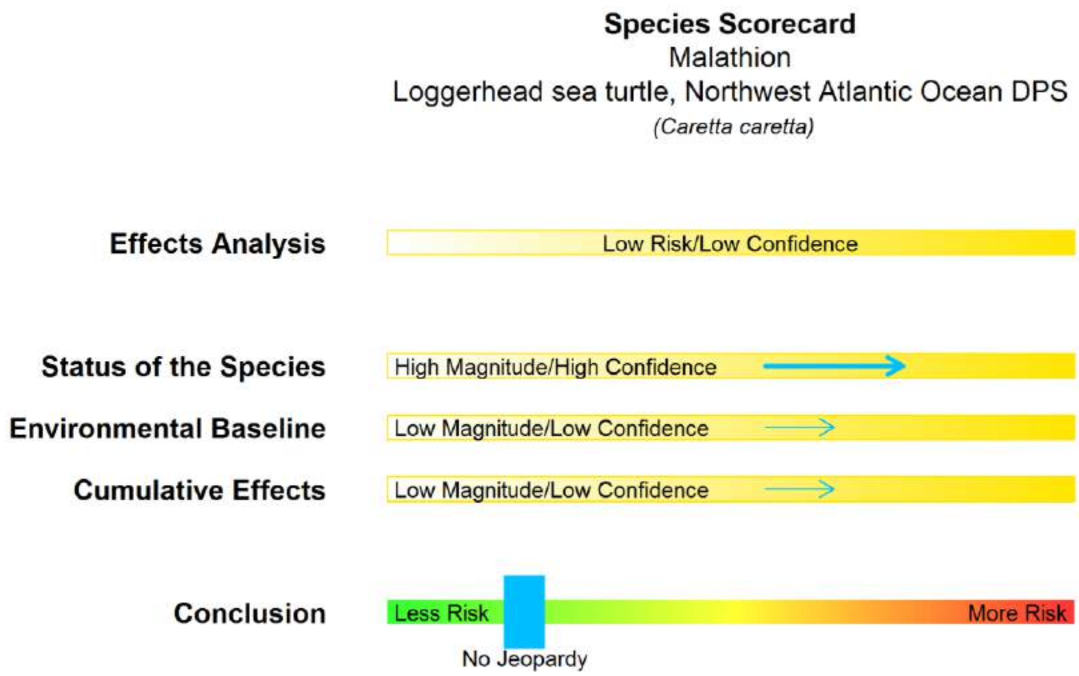

Figure 72. Species Score Card; Loggerhead sea turtle, Northwest Atlantic Ocean DPS; Malathion

Effects Analysis: Low risk/Low confidence

- Reduced abundance not anticipated
- Potential effects may include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- All sub-populations exhibiting negative population growth rates;
- Threatened;
- Recovery criteria not met;

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

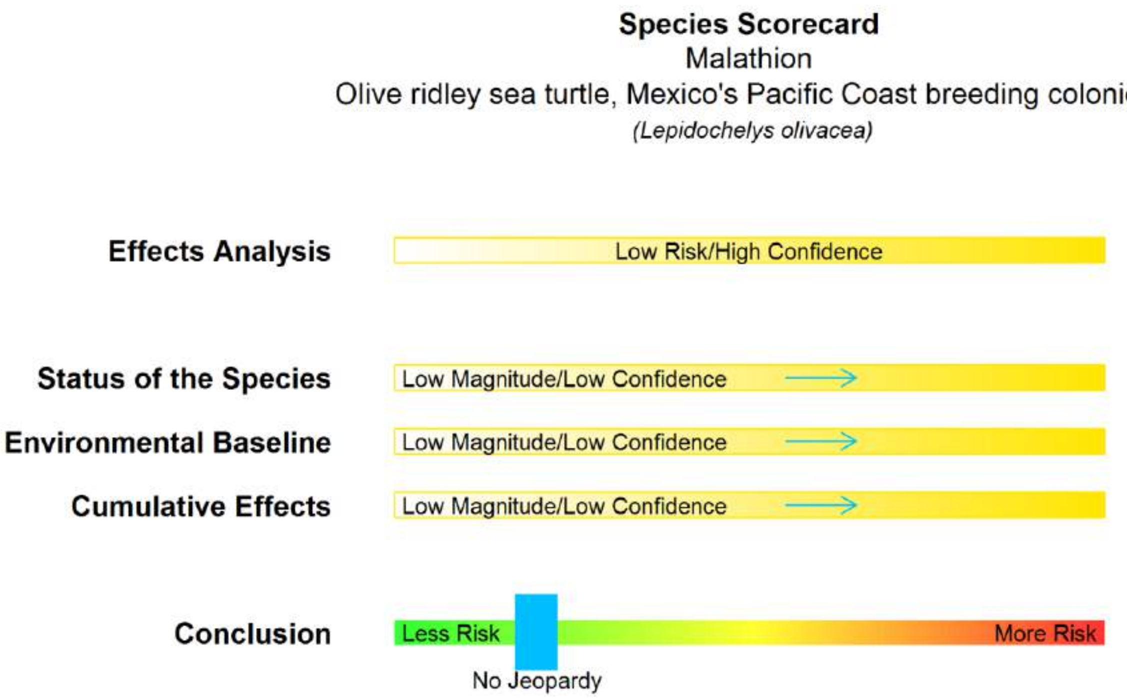

Figure 73. Species Score Card; Olive ridley sea turtle, Mexico's Pacific Coast breeding colonies; Malathion

<u>Effects Analysis: Low risk/High confidence</u>

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- 50% decline in a population abundance since the 1960's; 80% reductions in some nesting populations in the Western Atlantic Ocean since 1967;
- Threatened;
- Recovery criteria not met;

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters but effects uncertain

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

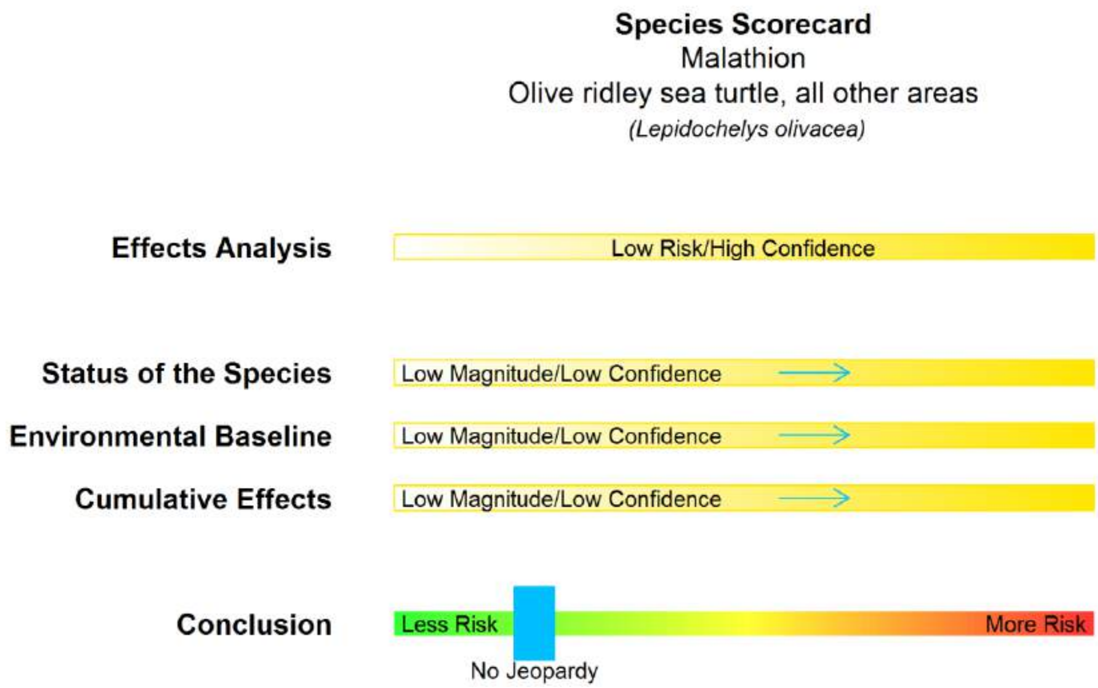

Figure 74. Species Score Card; Olive ridley sea turtle, all other areas; Malathion

Effects Analysis: Low risk/High confidence

- Reduced abundance not anticipated
- Potential effects include death; reduced cholinesterase activity, growth, and prey abundance; and impaired swimming.

Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Some nesting populations are stable or increasing, but most remain severely depressed. Populations are outside of the action area.
- Threatened;
- Recovery criteria not met;

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect turtles
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk while in shallow areas and rivers/streams. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

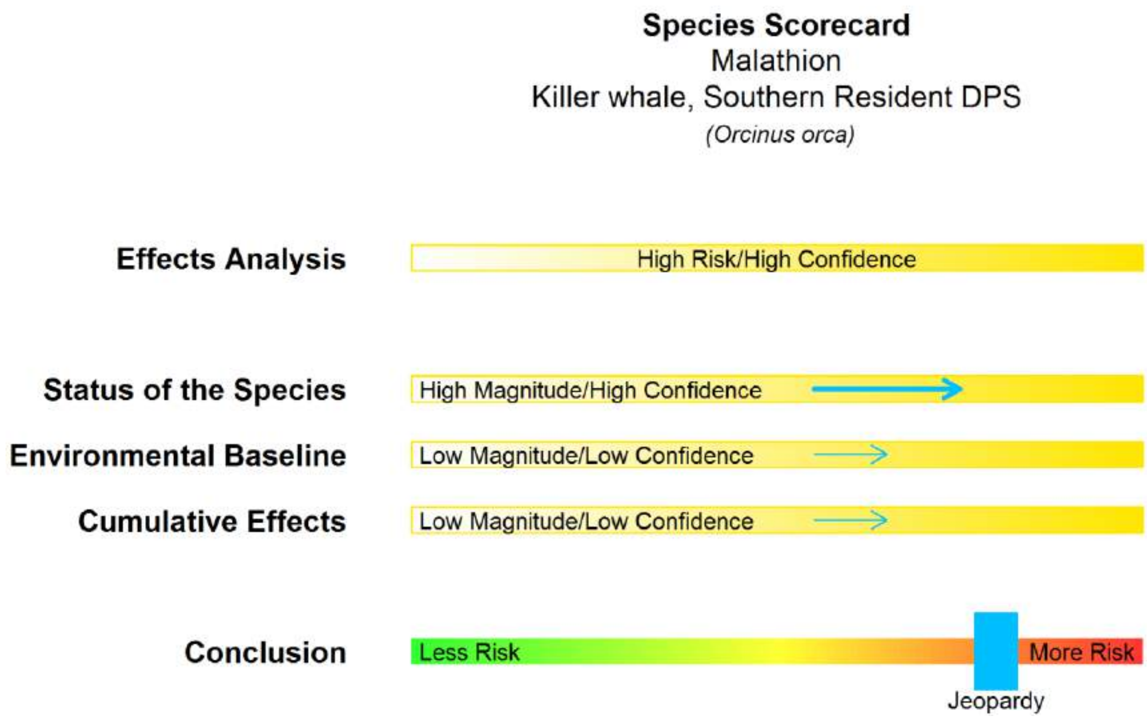

Figure 75. Species Score Card; Killer whale, Southern Resident DPS; Malathion

Effects Analysis: High risk/High confidence

- Reduced abundance anticipated based on effects to prey (Chinook salmon)
- Anticipated effects include reduced availability of Chinook salmon and other fish prey leading to reduced growth, chronic lack of food;

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- Stable to declining populations in past decade, unstable population structure
- Endangered, very small population size (n=76 individuals);
- Recovery criteria not met and reduced likelihood of attaining recovery goals

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/Low confidence

- Elevated temperatures may occur in marine habitats;
- Environmental mixtures anticipated in marine habitats with high uncertainty of toxicity

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures may occur in marine waters

Conclusion: In freshwater habitats, we find a high likelihood of exposure and effects to orca whales' prey base. We have high confidence in exposure concentrations predicted for freshwater habitats. The species prey is most at risk while spawning, rearing, and migrating in freshwaters. Reductions of species' numbers, reproduction, or distribution are anticipated over the 15-year action due to continuous reductions in prey.

Malathion is likely to jeopardize the continued existence of this species: Jeopardy

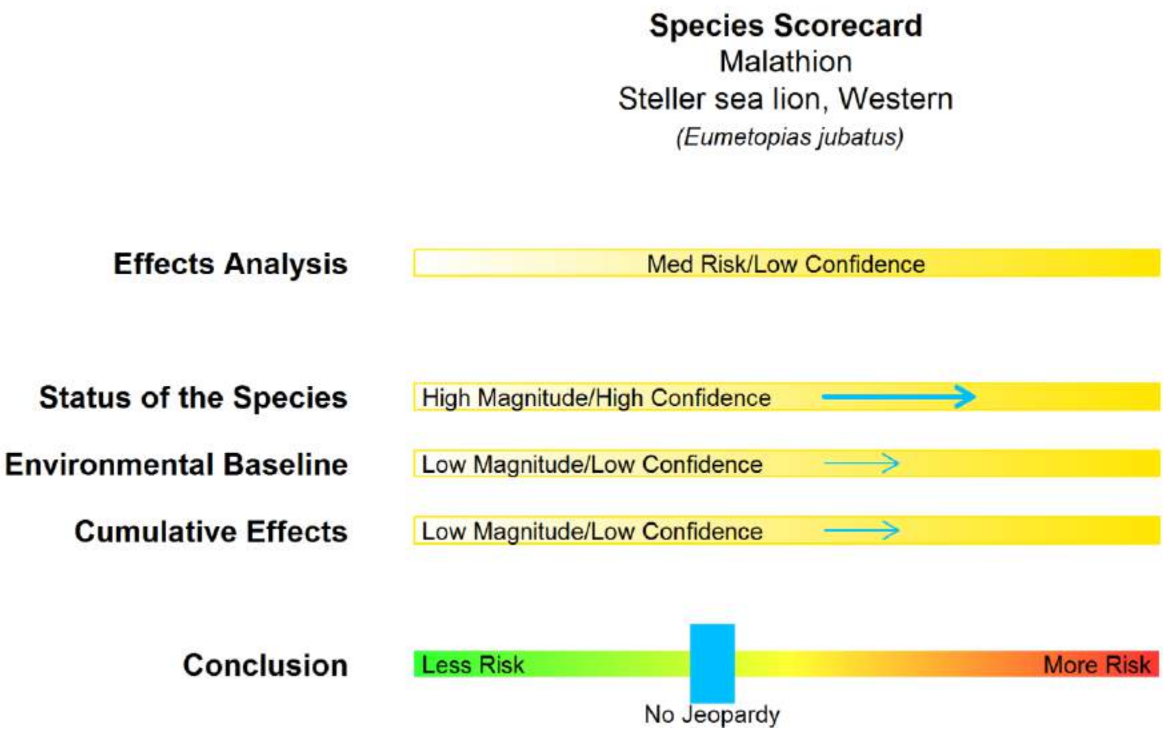

Figure 76. Species Score Card; Steller sea lion, Western; Malathion

Effects Analysis: Medium risk/Low confidence

- Reduced abundance not anticipated
- Potential effects include reduced prey abundance

Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence

- 30% of 1950s historical abundance, stable to slight negative population trend;
- Endangered;
- Recovery criteria not met;

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters unanticipated to affect sea lions
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk from reductions in prey. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

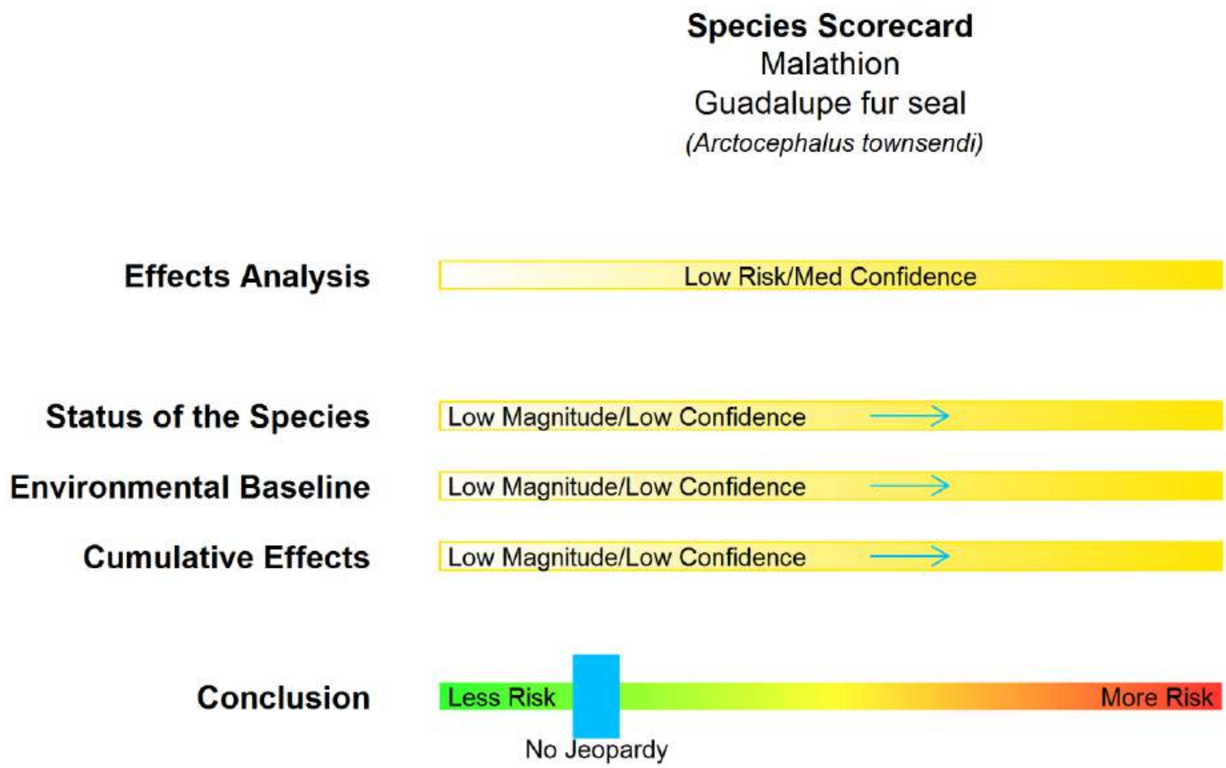

Figure 77. Species Score Card; Guadalupe fur seal; Malathion

<u>Effects Analysis: Low risk/Medium confidence</u>

- Reduced abundance not anticipated
- Potential effects include reduced prey abundance

<u>Status of the Species: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- 5% of historical abundance, increasing abundance trend;
- Threatened;
- No recovery criteria established;

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters not anticipated to affect sea lions
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters but effects uncertain

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk from reductions in prey. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

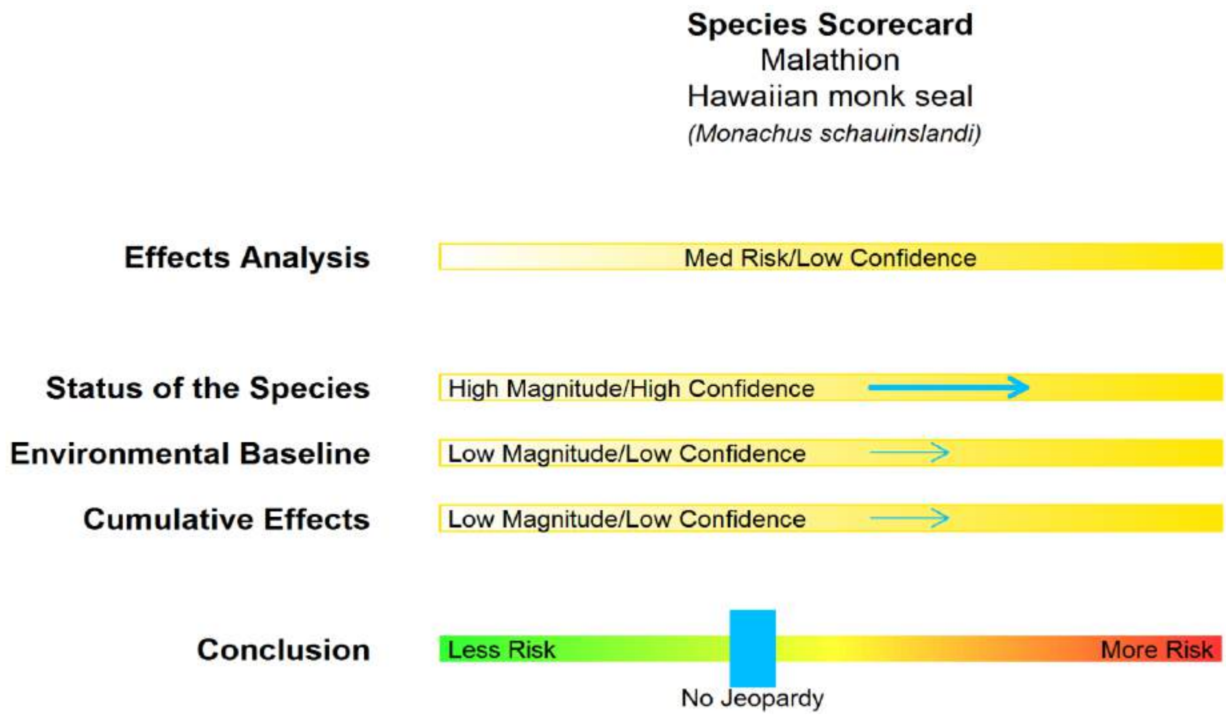

Figure 78. Species Score Card; Hawaiian monk seal; Malathion

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reduced abundance not anticipated
- Potential effects include reduced prey abundance

<u>Status of the Species: Increased risk of jeopardy; High magnitude/ High confidence</u>

- <40% of 1958 abundance, two populations have increasing trends, six populations have declining trends, very low genetic diversity
- Endangered;
- Recovery criteria not met

<u>Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Elevated temperatures in marine waters not anticipated to affect sea lions
- Environmental mixtures anticipated in marine waters yet effects uncertain

<u>Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence</u>

- Future elevated temperatures anticipated in marine waters but effects uncertain

<u>Conclusion:</u> In marine habitats, we find a small likelihood of exposure and effects to the species based on low confidence in exposure concentrations. The species is most at risk from reductions in prey. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

<u>Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy</u>

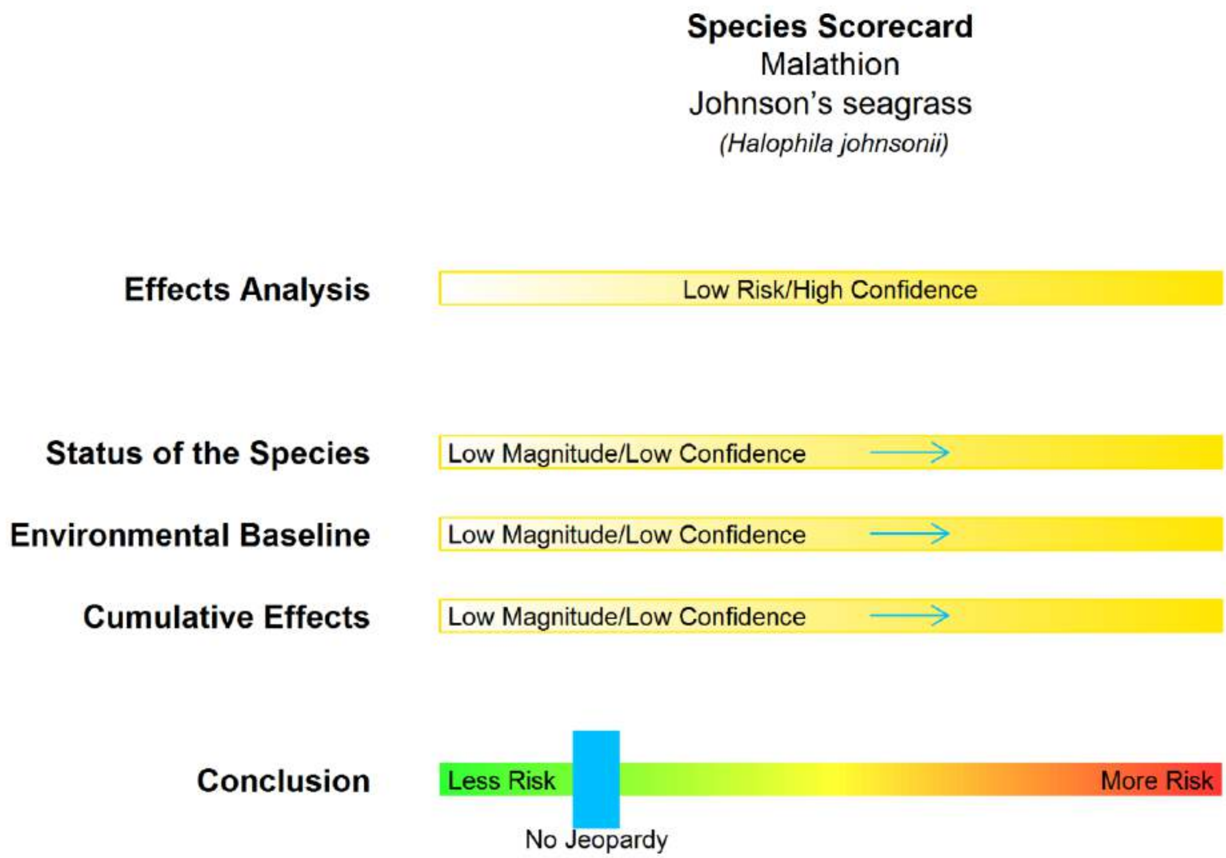

Figure 79. Species Score Card; Johnson's seagrass; Malathion

Effects Analysis: Low risk/High confidence

- Reduced abundance not anticipated

Status of the Species: Increased risk of jeopardy; Low magnitude/ Low confidence

- No trend data on abundance
- Threatened;
- Recovery criteria not met

Environmental Baseline: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Elevated temperatures in marine waters not anticipated to affect seagrass
- Environmental mixtures anticipated in marine waters yet effects uncertain

Cumulative Effects: Minimal increased risk of jeopardy; Low magnitude/ Low confidence

- Future elevated temperatures anticipated in marine waters but effects uncertain

Conclusion: In marine habitats, we find a high likelihood of exposure and a low likelihood of effects to the species based on low confidence in exposure concentrations and low toxicity. The species is most at risk from direct toxicity. Reductions of species' numbers, reproduction, or distribution are not anticipated over the 15-year action.

Malathion is not likely to jeopardize the continued existence of this species: No Jeopardy

CHAPTER 22

INTEGRATION AND SYNTHESIS FOR DESIGNATED CRITICAL HABITAT

CHLORPYRIFOS

TABLE OF CONTENTS

22 Chlorpyrifos

22.1 Introduction

The integration and synthesis section is the final step in our assessment of the risk posed to species and critical habitat as a result of implementing the proposed action. In this section, we add the effects of the action to the environmental baseline and the cumulative effects to formulate the agency's biological opinion as to whether the proposed action is likely to: (1) reduce appreciably the likelihood of both the survival and recovery of Endangered Species Act (ESA)-listed species in the wild by reducing its numbers, reproduction, or distribution; or (2) appreciably diminish the value of designated critical habitat for the conservation of an ESA-listed species. These assessments are made in full consideration of the Status of the Species.

We treat the information from the status of the species, environmental baseline, and cumulative effects, as "risk modifiers," in that the effects described in the effects analysis section may be modified by the condition of the species; the condition of environmental baseline, and the anticipated cumulative effects. The key questions addressed include:

- Status of Designated Critical Habitat:
  - Are the PBFs impaired or degraded?
- Environmental Baseline:
  - Are freshwater temperatures elevated?
  - Are pesticide environmental mixtures present, or anticipated based on current land use?
- Cumulative Effects:
  - Will future temperatures impair species aquatic habitats?
  - Will future hydrologic flows impair freshwater species habitats?
  - How might changes in ocean conditions affect the species habitat?

As detailed in the environmental baseline and cumulative effects chapters, adverse toxic responses to exposures to these OP pesticides are heightened with increases in temperature. In addition, exposures to other pesticides in the environment can cause additive or synergistic responses when simultaneously exposed to any of these OPs. Altered hydraulic flows can cause migratory blockages. Lower hydraulic flows can also result in increases in water temperatures and reductions in dissolved oxygen levels. These conditions can put stress on aquatic species and increases toxic responses when exposed to these pesticides.

Once each of the above sections is evaluated i.e., questions answered, the effects of the action and the risk modifiers are depicted graphically on a "scorecard." First, we assign a magnitude of influence (small or large) indicated graphically with one of two lengths of arrows. The shorter of the two arrows indicates a low magnitude, while the longer of the two arrows indicates a high magnitude as a risk modifier. The direction an arrow is pointed indicates the directionality of the risk modifier. For example, an environmental baseline arrow pointing towards more risk may indicate that environmental mixtures and elevated temperatures occur in the Environmental Baseline, which further stresses the species in question. We also assign a level of confidence in our selection of the small and large magnitude, indicated by a bold arrow (high confidence) or an un-bolded arrow (low confidence). The final arrow representing the influence on risk is graphically depicted on each of the designated critical habitat scorecards.

Figure 1. Example of arrows to represent direction, magnitude, and confidence of risk modifiers

Conclusion Section:
We combine the effects analysis conducted in chapters 15 – 17 with the baseline status of the species habitat, and cumulative effects to determine whether the action could reasonably be expected to appreciably diminish the conservation value of designated critical habitat. We state our conclusion as to whether the action is likely to destroy or adversely modify each of the species designated critical habitats.

A scorecard is generated for each species designated critical habitat. The effects of the proposed action is considered based on magnitude and confidence of the three arrows. Next, an adverse modification or no adverse modification vertical blue bar is placed on the horizontal risk bar i.e., the colored bar beginning with green (less risk) to red (more risk) (***Figure 2***) to depict our conclusion.

Figure 2: Example conclusion graphic

22.2 Designated Critical Habitat Scorecards (Chlorpyrifos)

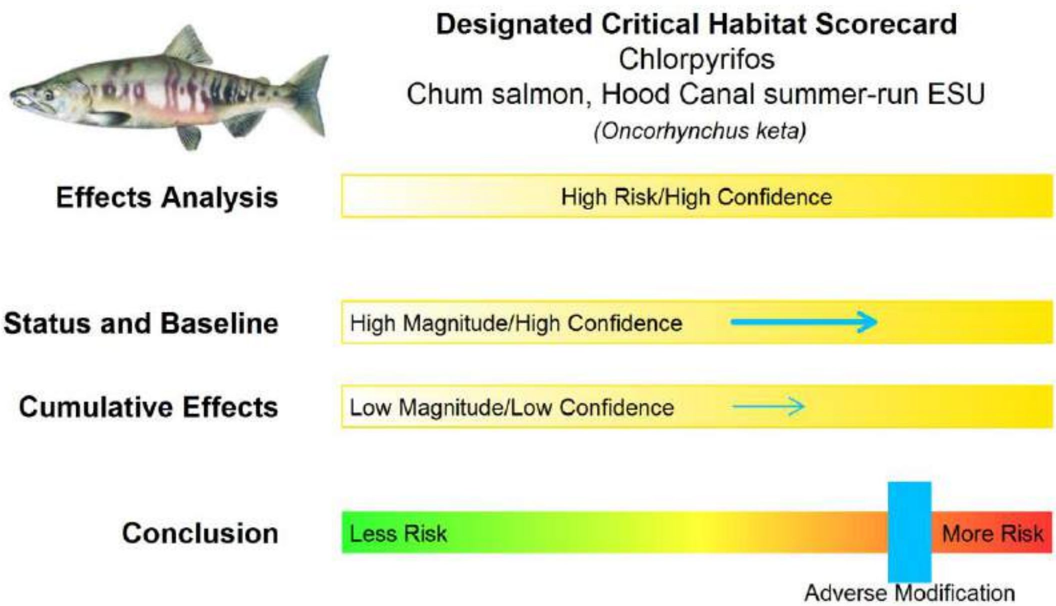

Figure 3. Designated Critical Habitat Scorecard; Chum salmon, Hood Canal summer-run Evolutionarily Significant Unit (ESU); Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded
- Migration and rearing PBFs are impaired by loss of floodplain habitat necessary for juvenile growth and development
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- All 12 watersheds of high or medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Sixteen use site categories, totaling more than 437,951 acres (over 31% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

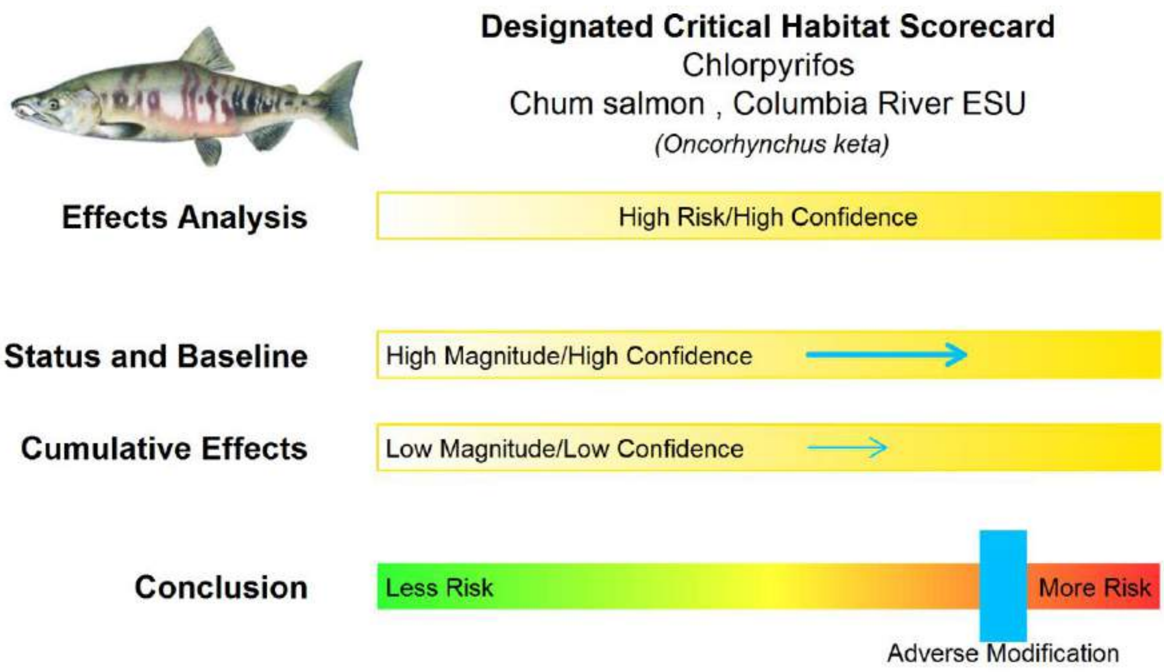

Figure 4. Designated Critical Habitat Scorecard; Chum salmon, Columbia River ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs (water quality and cover) are degraded
- Migration PBFs significantly impacted by dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- All 19 watersheds of high or medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Fourteen use site categories, totaling more than 852,477 acres (over 58% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

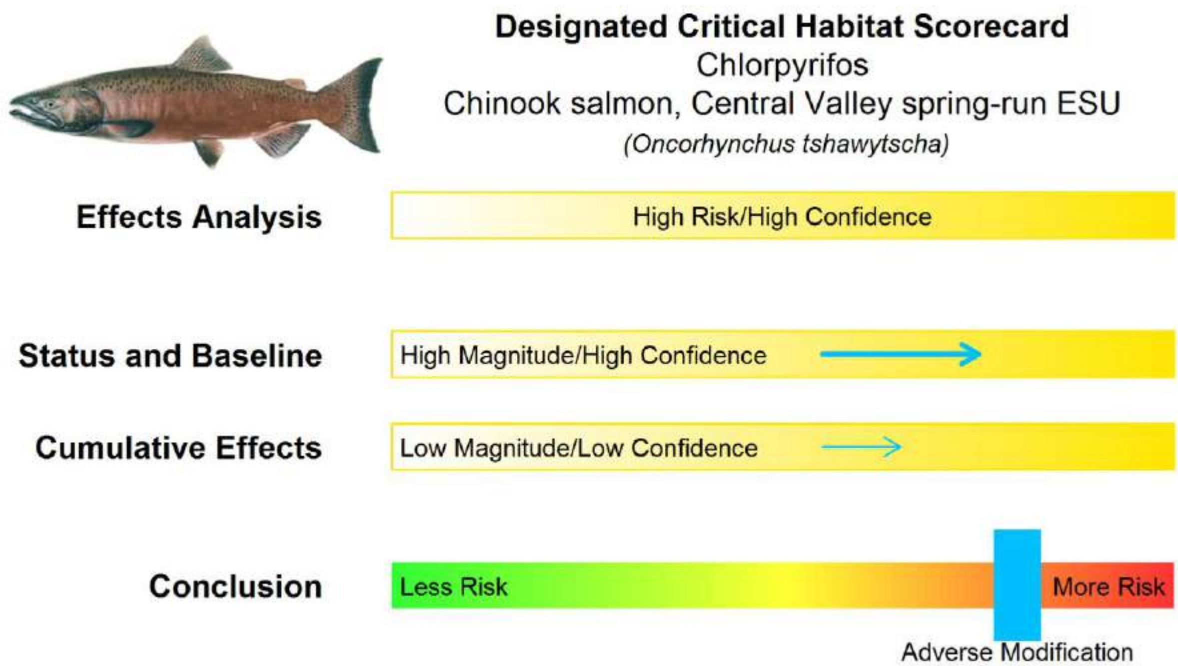

Figure 5. Designated Critical Habitat Scorecard; Chinook salmon, Central Valley spring-run ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by elevated temperatures, lost access to historic spawning sites, and loss of floodplain habitat
- Migration PBFs degraded by loss of cover and water diversions
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 38 watersheds, 28 are of high and 3 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Sixteen use site categories, totaling more than 2,211,697 acres (over 65% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

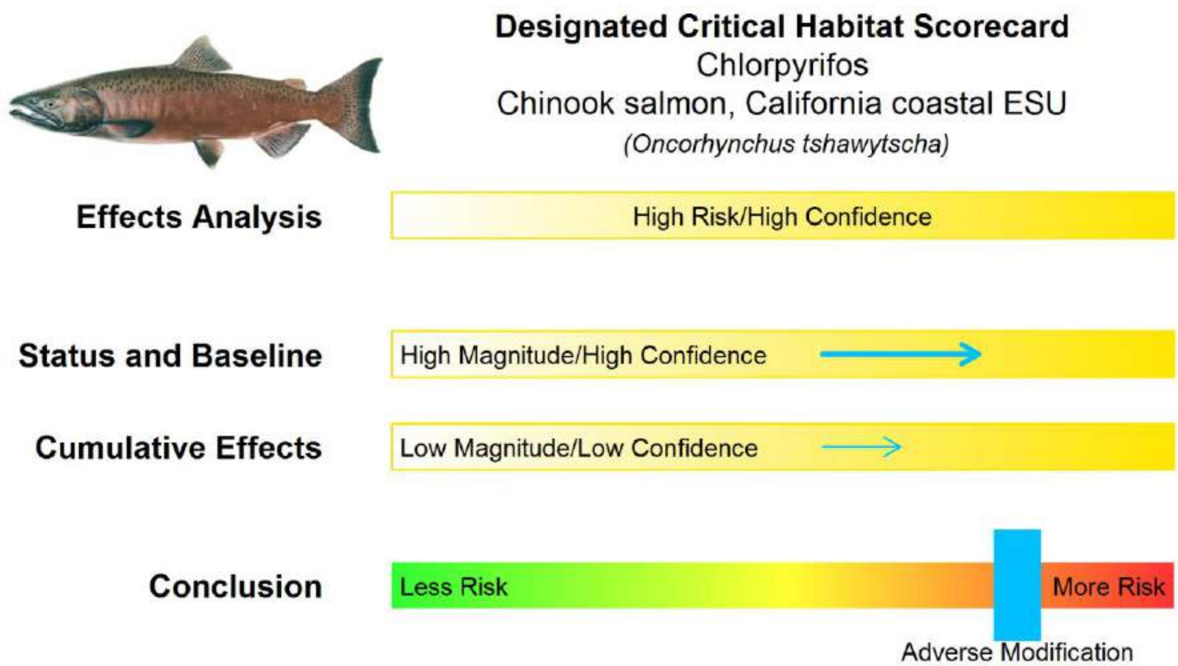

Figure 6. Designated Critical Habitat Scorecard; Chinook salmon, California coastal ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning PBFs are degraded by timber harvest
- Rearing and migration PBFs impacted by dams and invasive species.
- Estuarine PBFs degraded by water quality and saltwater mixing
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 45 watersheds, 27 are of high and 10 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Fifteen use site categories, totaling more than 899410 acres (over 16% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

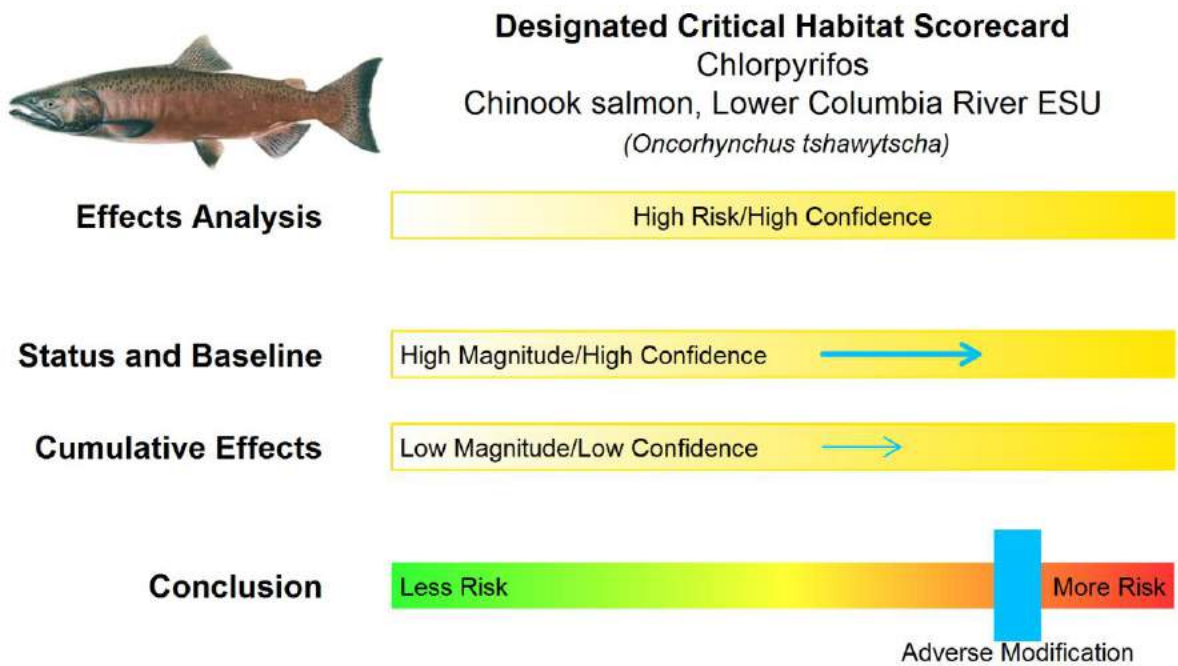

Figure 7. Designated Critical Habitat Scorecard; Chinook salmon, Lower Columbia River ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by timber harvest, agriculture, urbanization, loss of floodplain habitat, and reduced natural cover
- Migration PBFs impacted by dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of occupied watersheds, 31 are of high and 13 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 1,949,214 acres (over 62% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

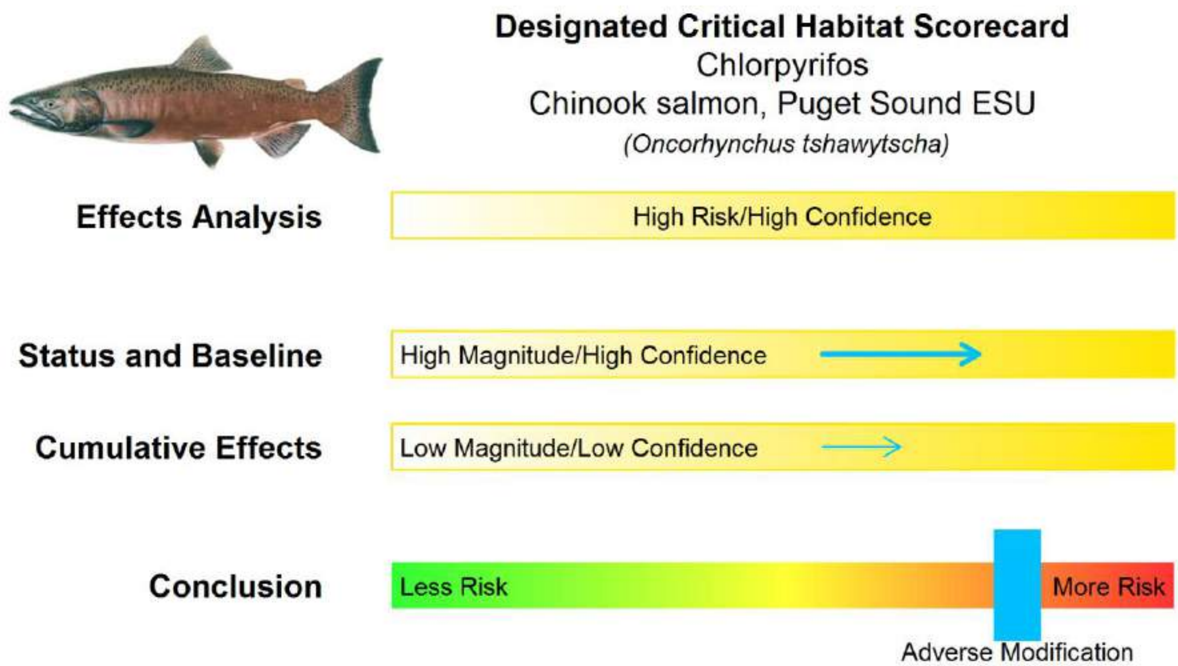

Figure 8. Designated Critical Habitat Scorecard; Chinook salmon, Puget Sound ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Spawning, rearing and migration PBFs are degraded by forestry, agriculture, urbanization, and loss of habitat
- Estuarine PBFs degraded by water quality, altered salinity, and lack of natural cover
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 61 watersheds, 40 are of high and 9 are of medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Sixteen use site categories, totaling more than 4,249,639 acres (over 45% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

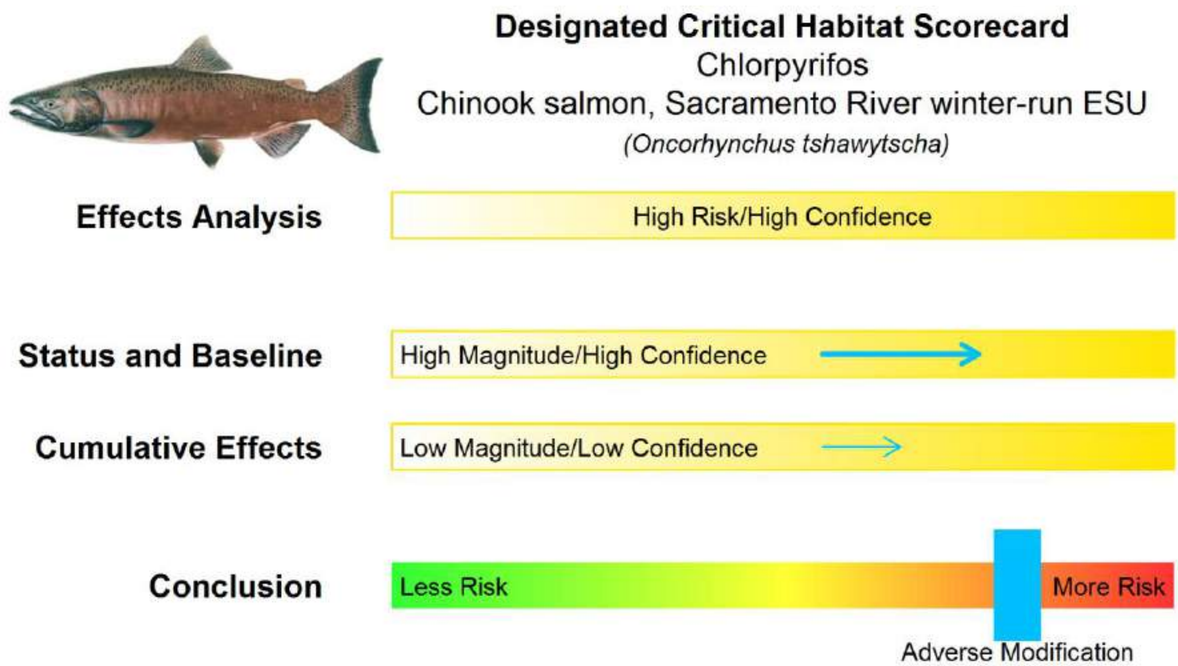

Figure 9. Designated Critical Habitat Scorecard; Chinook salmon, Sacramento River winter-run ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by elevated temperatures and loss of habitat
- Migration PBFs degraded by lack of natural cover and water diversions
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire Sacramento river and delta are considered of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Sixteen use site categories, totaling more than 1,060,503 acres (over 71% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

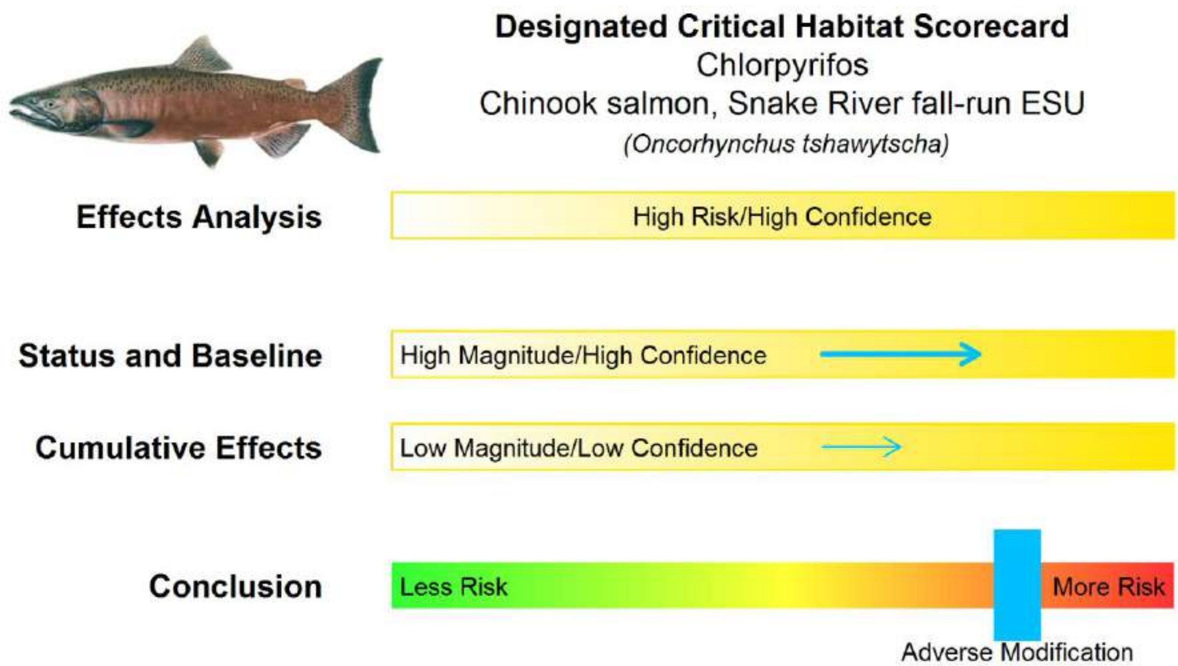

Figure 10. Designated Critical Habitat Scorecard; Chinook salmon, Snake River fall-run ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, rearing and migration PBFs are degraded by loss of habitat, impaired stream flows, barriers to fish passage, and poor water quality
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire river corridor is considered of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 5,462,029 acres (over 66% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

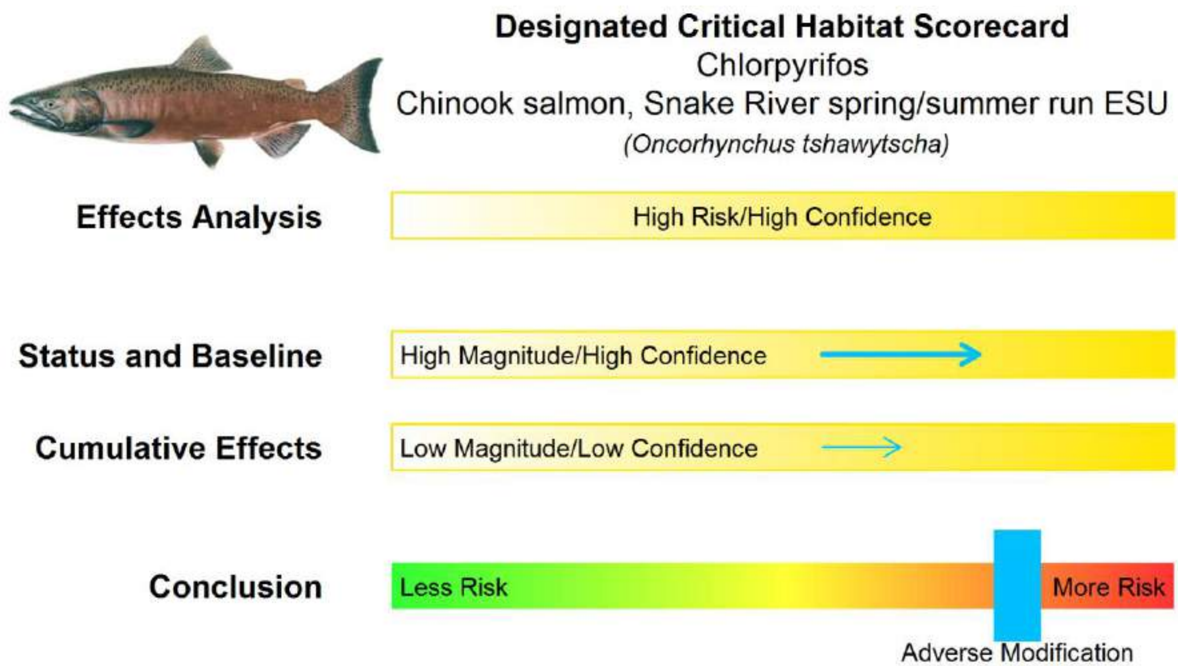

Figure 11. Designated Critical Habitat Scorecard; Chinook salmon, Snake River spring/summer run ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Spawning, rearing and migration PBFs are degraded by loss of habitat, altered stream flows, barriers to fish passage, dams, loss of cover, and poor water quality
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire river corridor is considered of high conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 7,267,721 acres (over 50% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

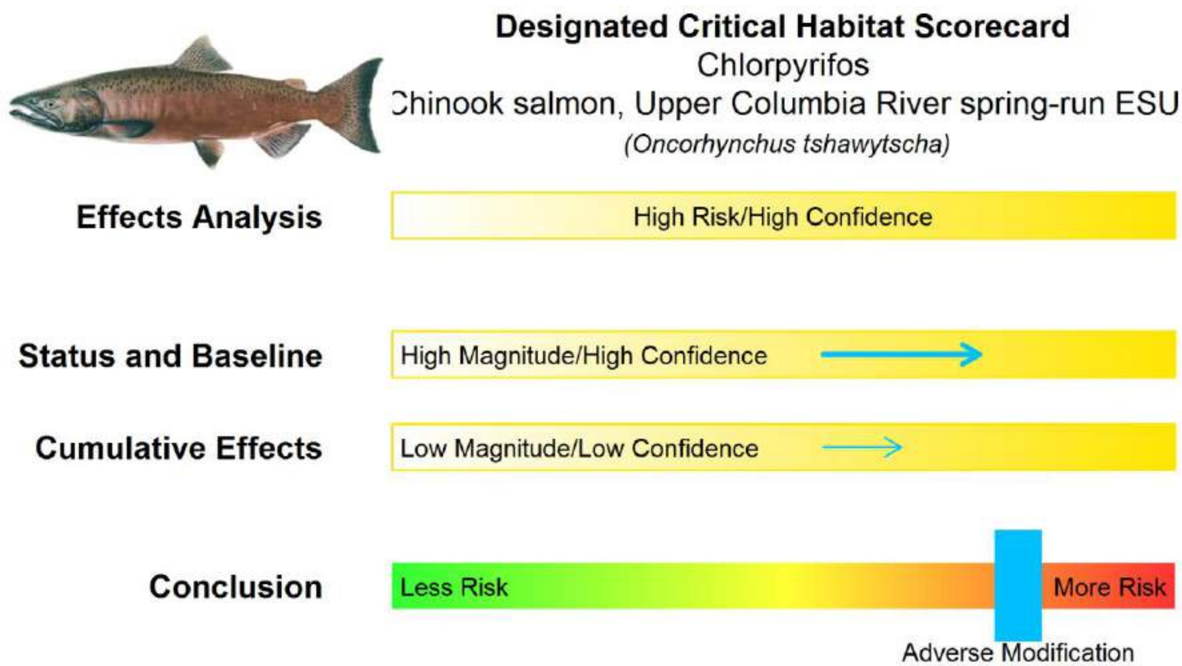

Figure 12. Designated Critical Habitat Scorecard; Chinook salmon, Upper Columbia River spring-run ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by urbanization and irrigation water diversions
- Migration PBFs degraded by numerous dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of occupied watersheds, 26 are of high and 5 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 1,512,434 acres (over 48% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

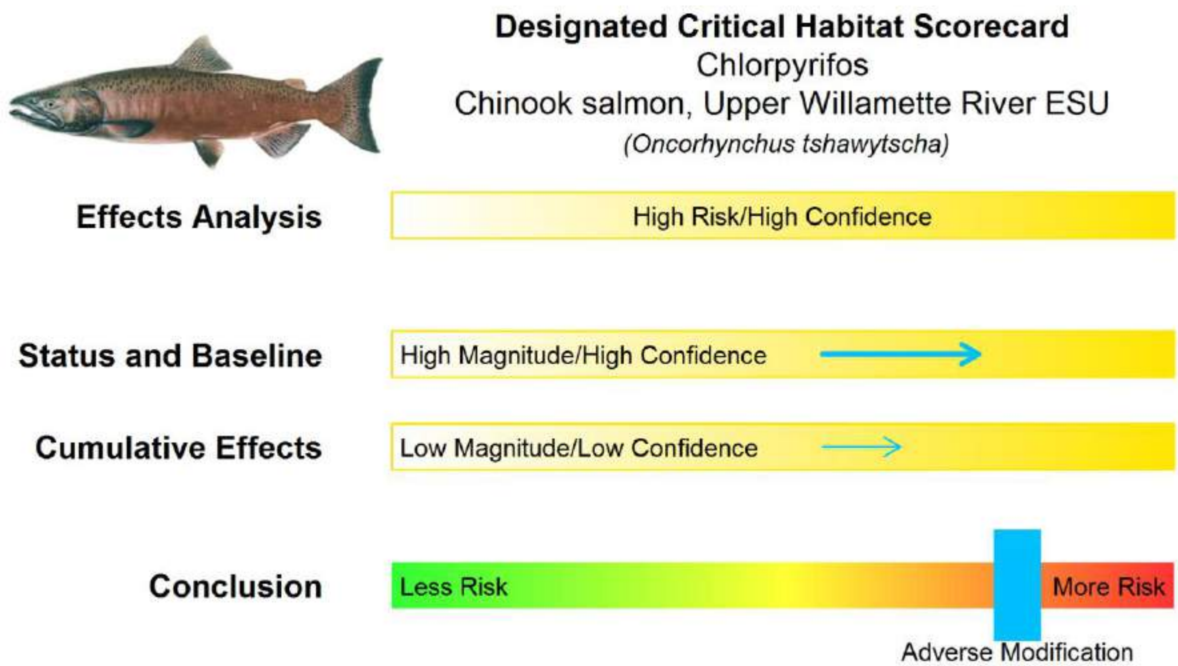

Figure 13. Designated Critical Habitat Scorecard; Chinook salmon, Upper Willamette River ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Migration, rearing, and estuary PBFs are degraded by dams, water management, loss of riparian vegetation, and quality of floodplain habitat
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 59 assessed watersheds, 22 are of high and 18 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 2,564,130 acres (over 74% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

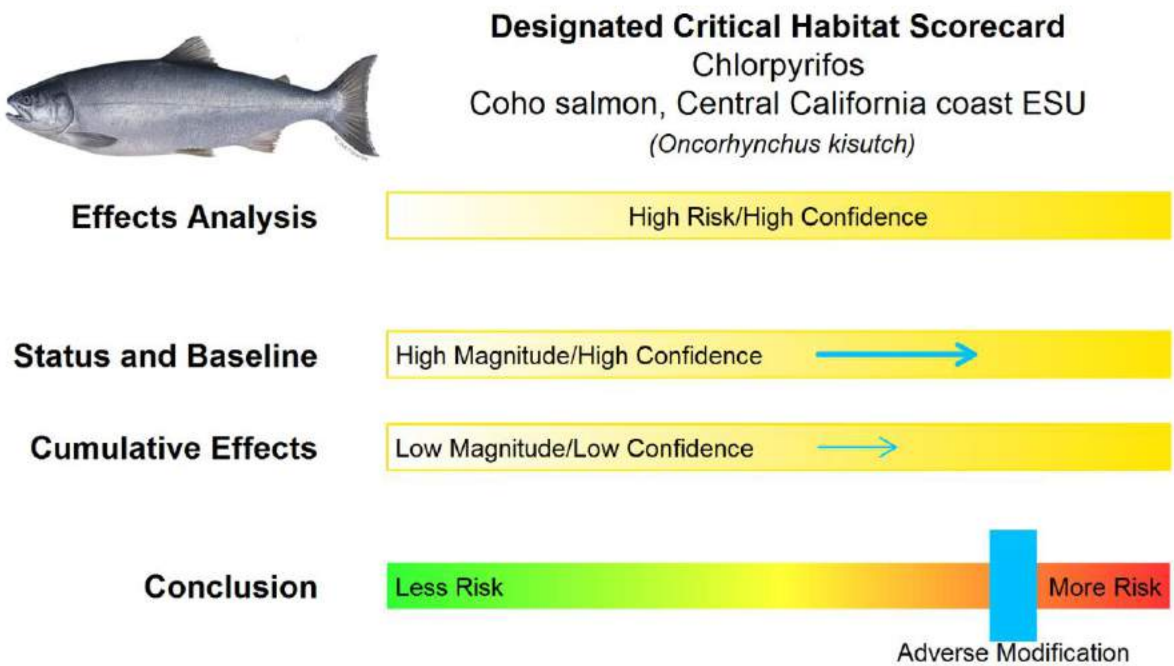

Figure 14. Designated Critical Habitat Scorecard; Coho salmon, Central California coast ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Degradation in quality and quantity of PBFs, especially in southern end of range
- Rearing PBFs degraded by loss of suitable incubation substrate and loss of habitat
- Elevated temperatures anticipated in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats may impact PBFs

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Sixteen use site categories, totaling more than 1,351,070 acres (over 35% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

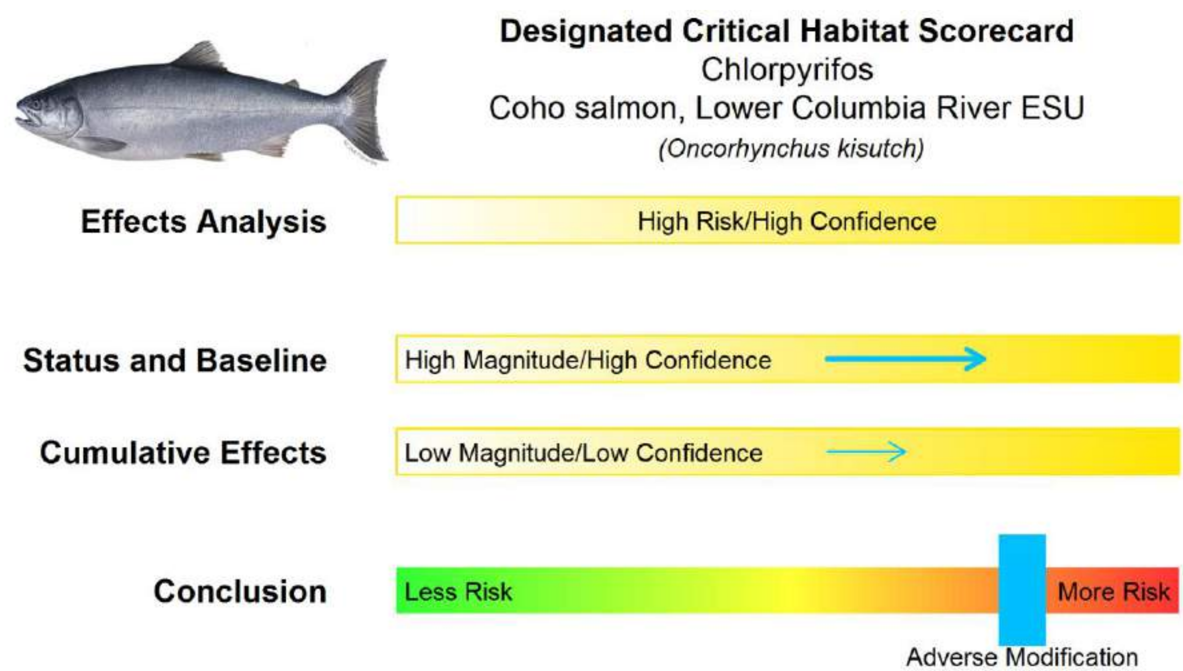

Figure 15. Designated Critical Habitat Scorecard; Coho salmon, Lower Columbia River ESU; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Spawning and rearing PBFs are degraded by timber harvest, agriculture, urbanization, loss of floodplain habitat, and reduced natural cover
- Migration PBFs impacted by dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 2,903,477 acres (over 62% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

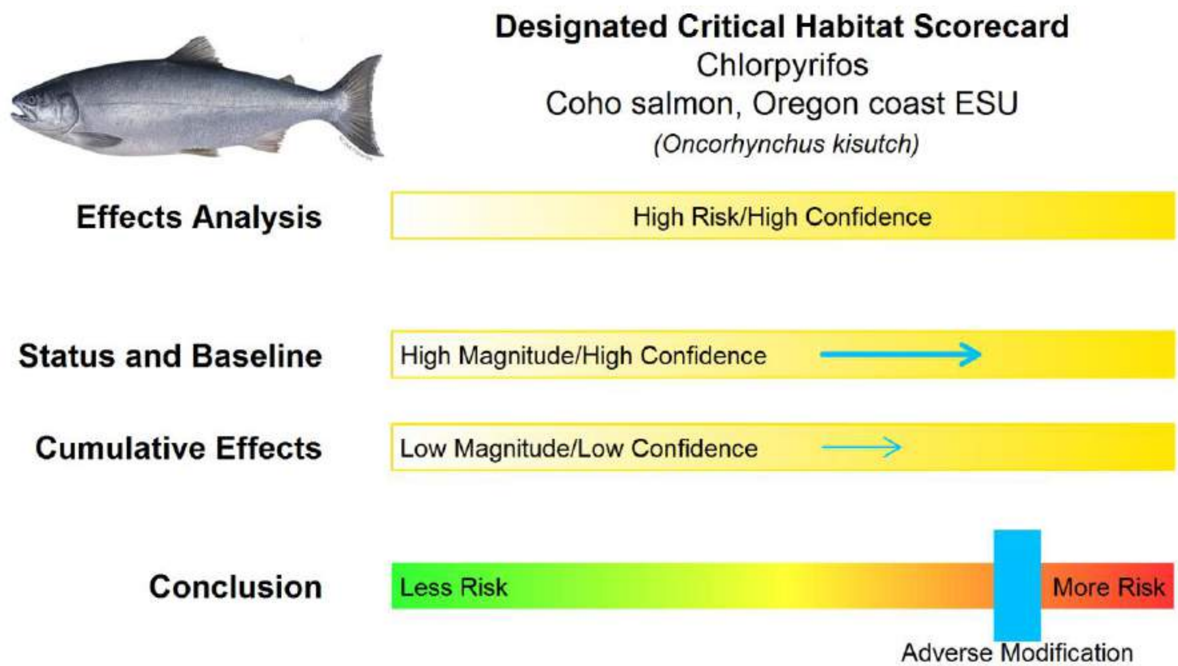

Figure 16. Designated Critical Habitat Scorecard; Coho salmon, Oregon coast ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by elevated water temperature
- All PBFs degraded by reduced water quality from contaminants and excess nutrients
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 80 assessed watersheds, 45 are of high and 27 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Sixteen use site categories, totaling more than 4,171,280 acres (over 66% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

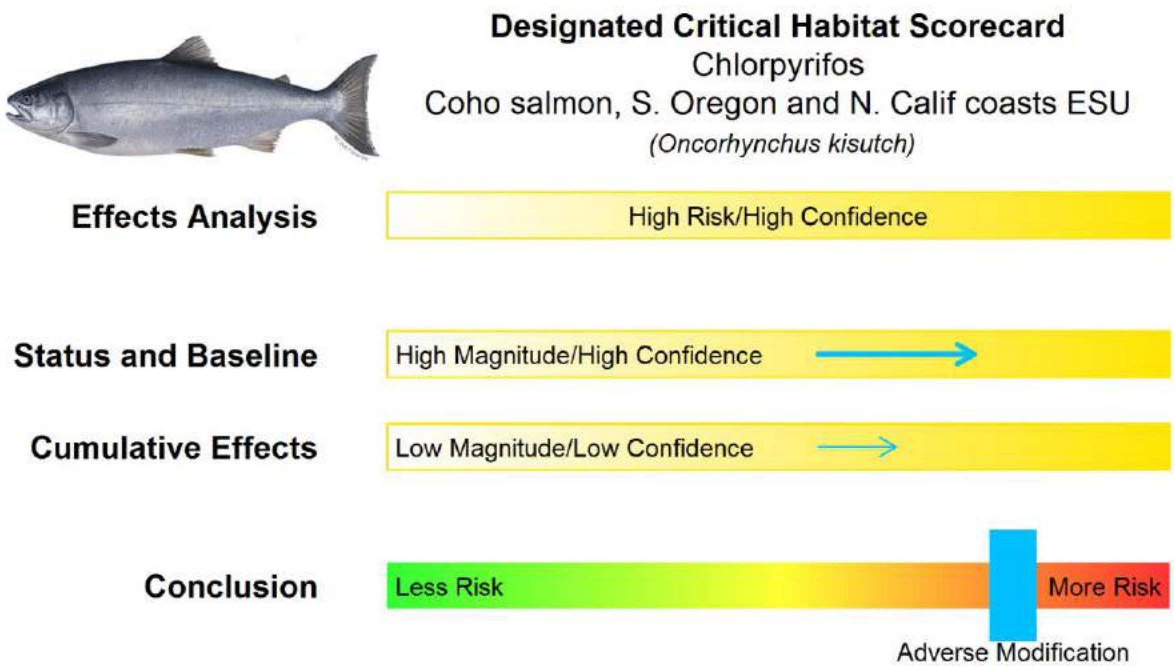

Figure 17. Designated Critical Habitat Scorecard; Coho salmon, S. Oregon and N. Calif coasts ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning PBFs are degraded by logging
- Rearing and migration PBFs degraded by loss of riparian vegetation and loss of floodplain habitat
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Fifteen use site categories, totaling more than 6,444,382 acres (over 46% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

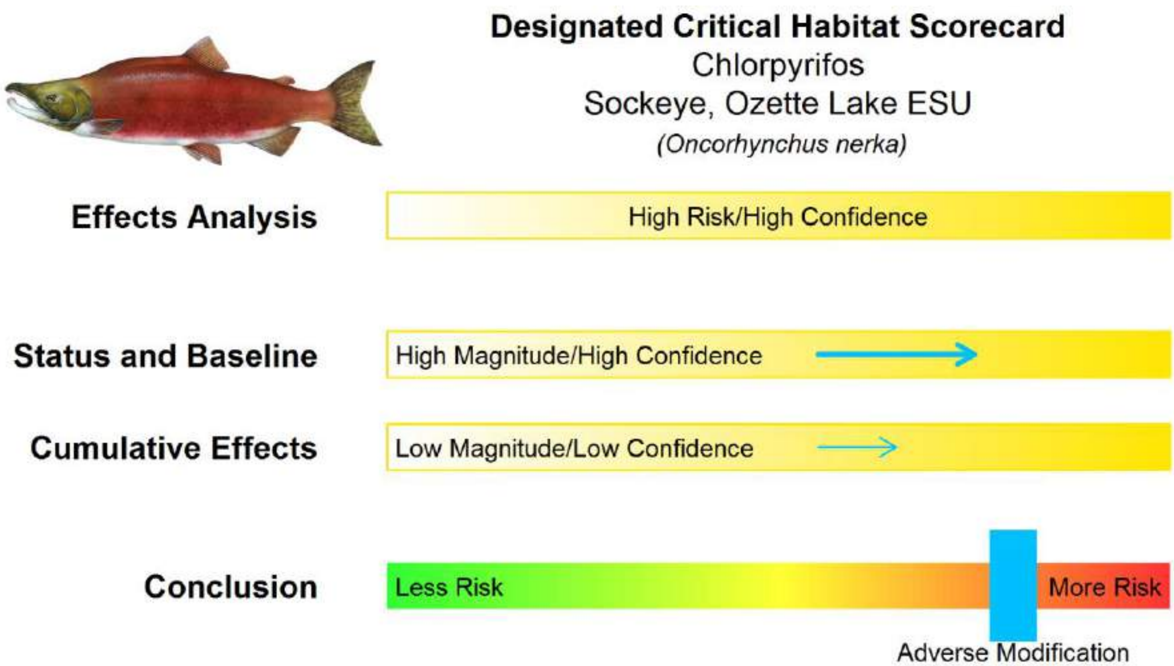

Figure 18. Designated Critical Habitat Scorecard; Sockeye, Ozette Lake ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by excessive predation, invasive species, and loss of habitat
- Spawning and migration PBFs are degraded by low water levels, loss of suitable spawning habitat, and low summer water flows
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire watershed is of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Six use site categories, totaling more than 25,949 acres (over 45% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

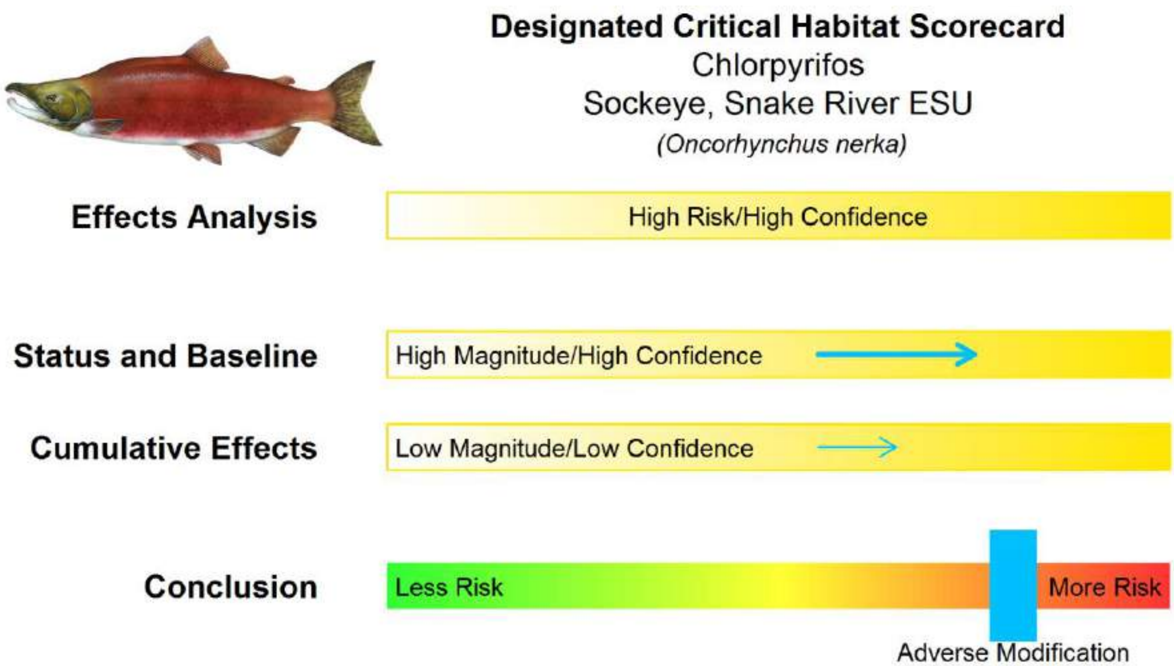

Figure 19. Designated Critical Habitat Scorecard; Sockeye, Snake River ESU; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing and migration PBFs are degraded by impaired water quality from adjacent land uses
- Migration PBFs are degraded by multiple dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- All occupied and used areas of the watershed are of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 1,710,031 acres (over 54% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

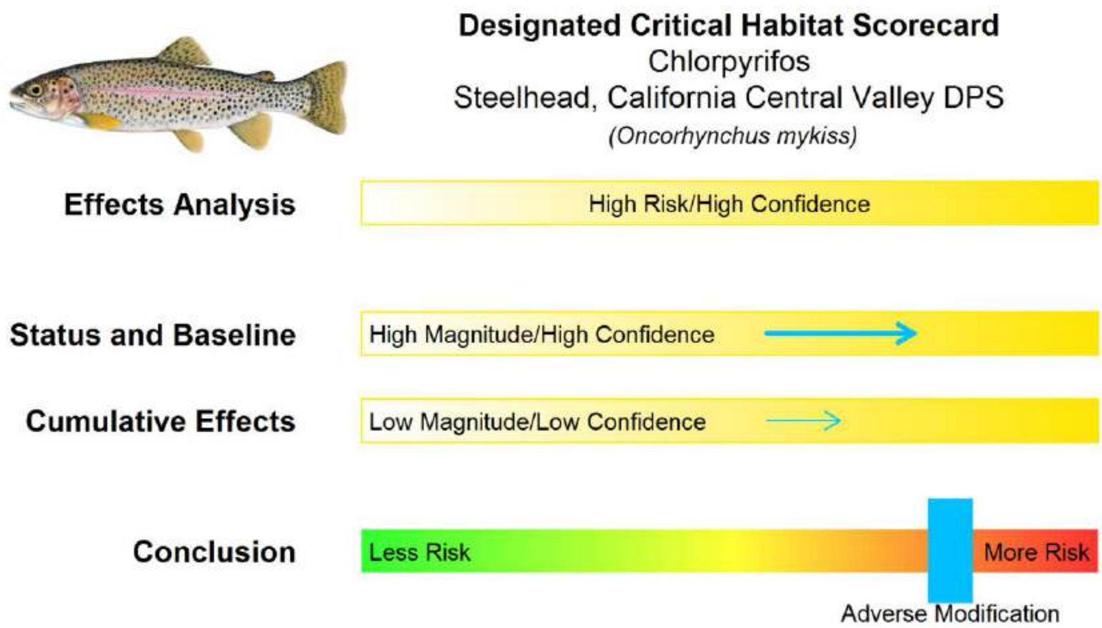

Figure 20. Designated Critical Habitat Scorecard; Steelhead, California Central Valley Distinct Population Segment (DPS); Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning physical and biological features (PBFs) are degraded by altered water flows and temperature
- Rearing and migration PBFs are degraded by altered riverine habitat, dense urbanization and agriculture, poor water quality, and water diversions
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 67 occupied watersheds, 37 are of high and 18 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 4,080,477 acres (over 75% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

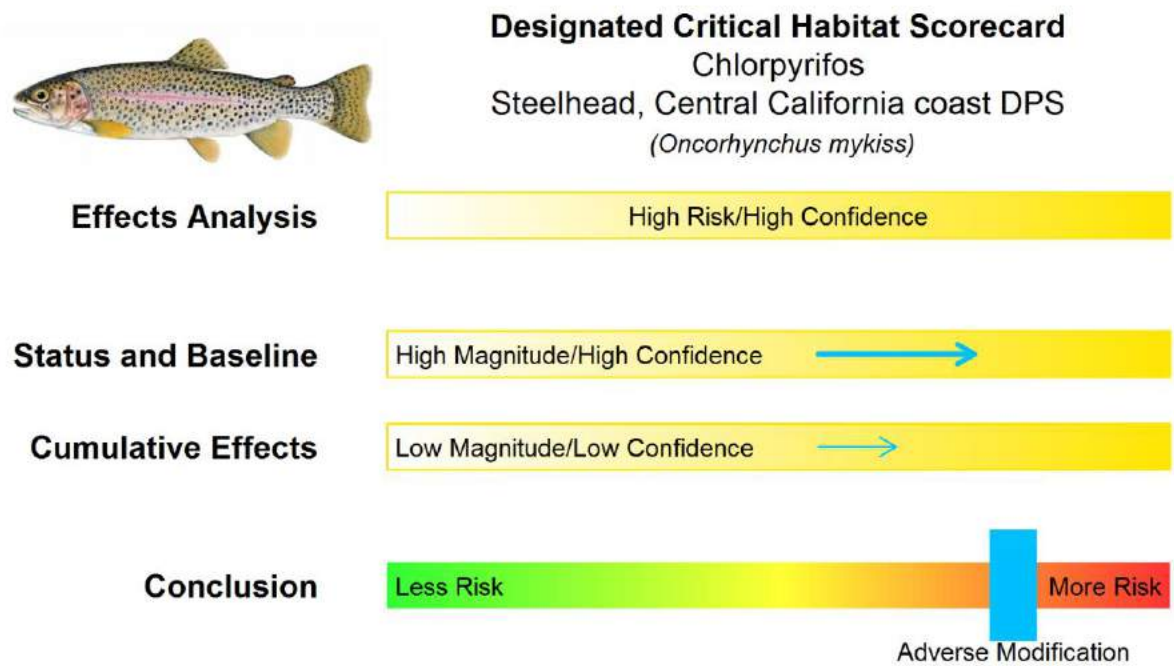

Figure 21. Designated Critical Habitat Scorecard; Steelhead, Central California coast DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by sedimentation and elevated temperature
- All PBFs are degraded by loss of habitat, low summer flows, erosion, and contaminants
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 47 occupied watersheds, 19 are of high and 15 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Sixteen use site categories, totaling more than 3,314,460 acres (over 45% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

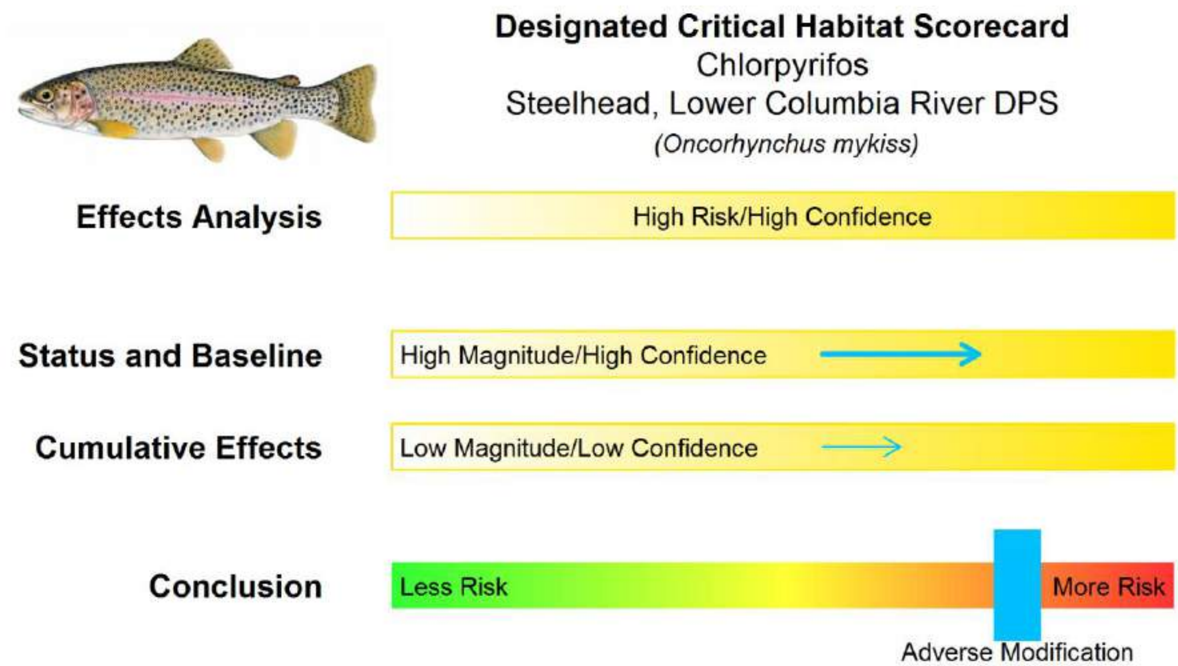

Figure 22. Designated Critical Habitat Scorecard; Steelhead, Lower Columbia River DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by agricultural runoff and lack of available prey
- Spawning, rearing and migration PBFs are degraded by timber harvests, dams, and loss of floodplain habitat
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 41 occupied watersheds, 28 are of high and 11 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 2,323,028 acres (over 63% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

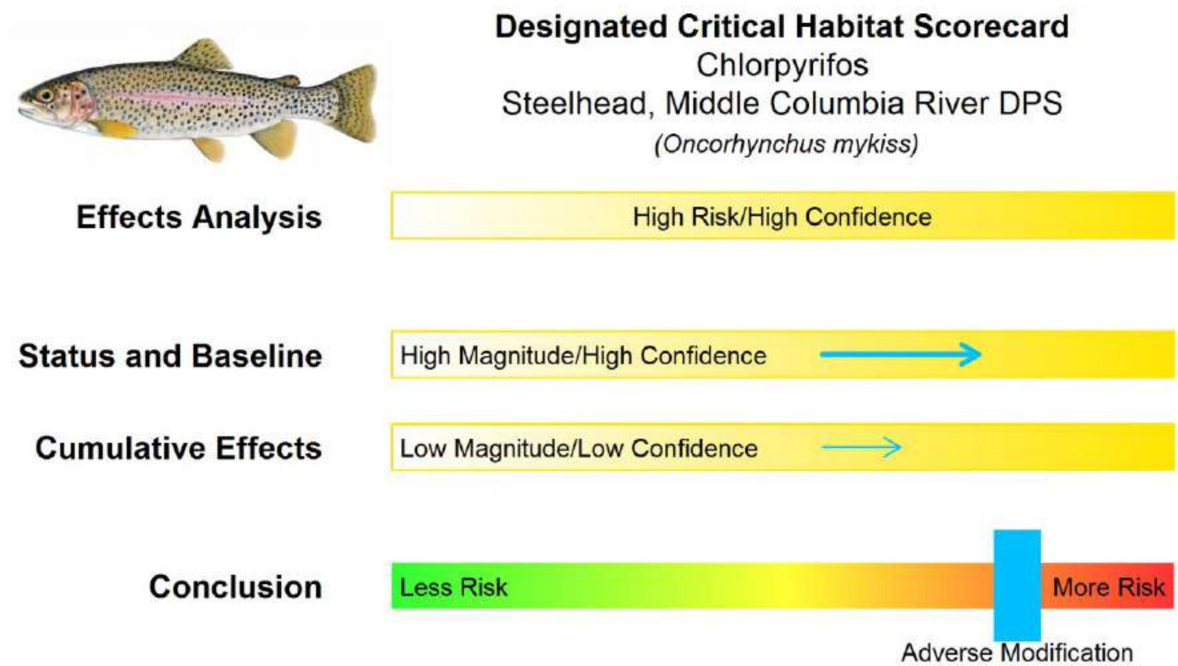

Figure 23. Designated Critical Habitat Scorecard; Steelhead, Middle Columbia River DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Rearing PBFs are degraded by water quality, reduced invertebrate prey, and loss of riparian vegetation
- Migration PBFs are degraded by several dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 106 assessed watersheds, 73 are of high and 24 are of medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 5,920,763 acres (over 45% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

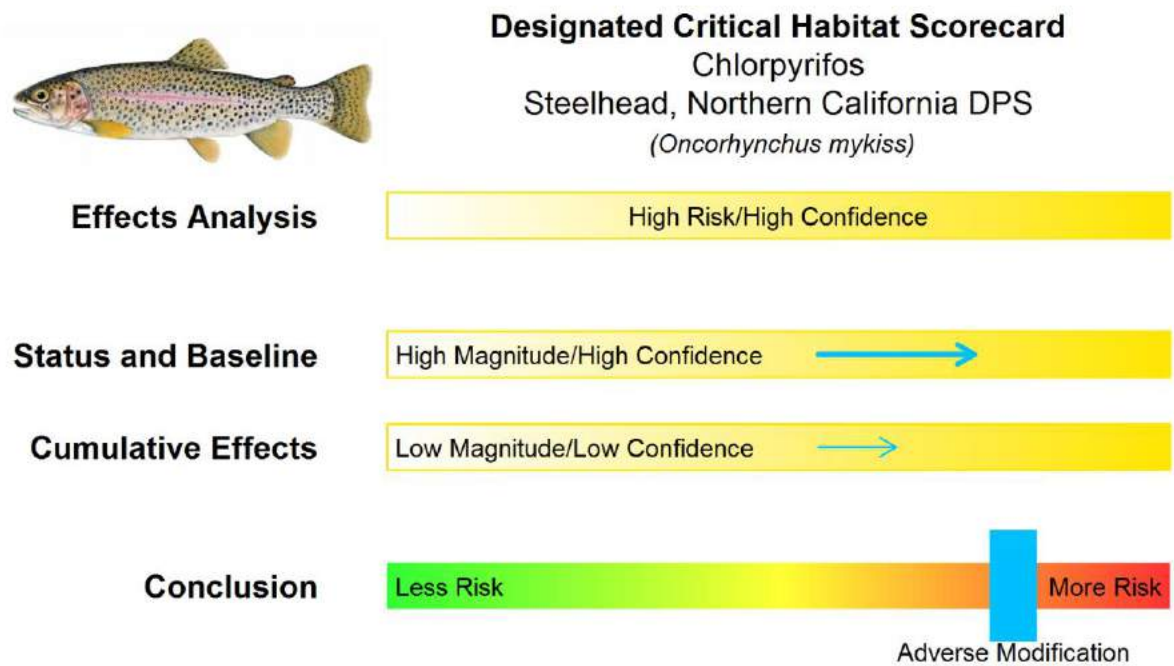

Figure 24. Designated Critical Habitat Scorecard; Steelhead, Northern California DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by loss of riparian vegetation and elevated temperature
- Spawning PBFs are degraded by lack of quality substrate and sedimentation
- Migration PBFs are degraded by bridges, culverts, and forest road construction
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 50 assessed watersheds, 27 are of high and 14 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Fourteen use site categories, totaling more than 1,019,525 acres (over 21% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

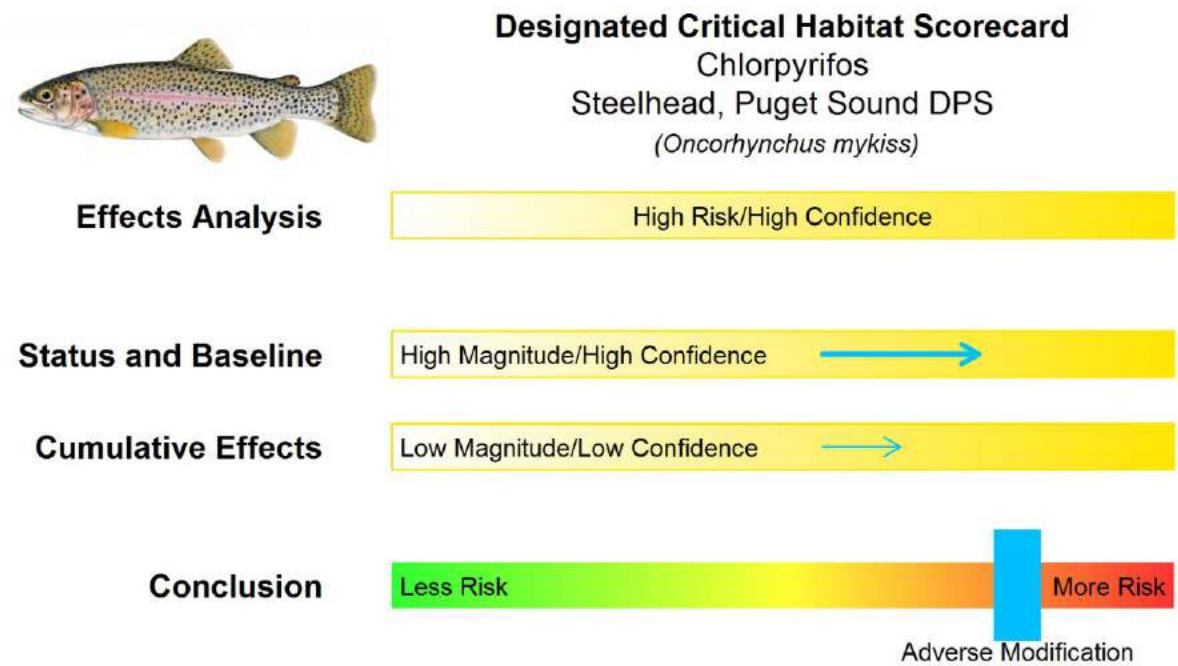

Figure 25. Designated Critical Habitat Scorecard; Steelhead, Puget Sound DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing, migration and spawning PBFs are degraded by forestry, agriculture, urbanization, loss of floodplain habitat, and poor water quality
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Most watersheds are of high or medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Sixteen use site categories, totaling more than 3,819,637 acres (over 63% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

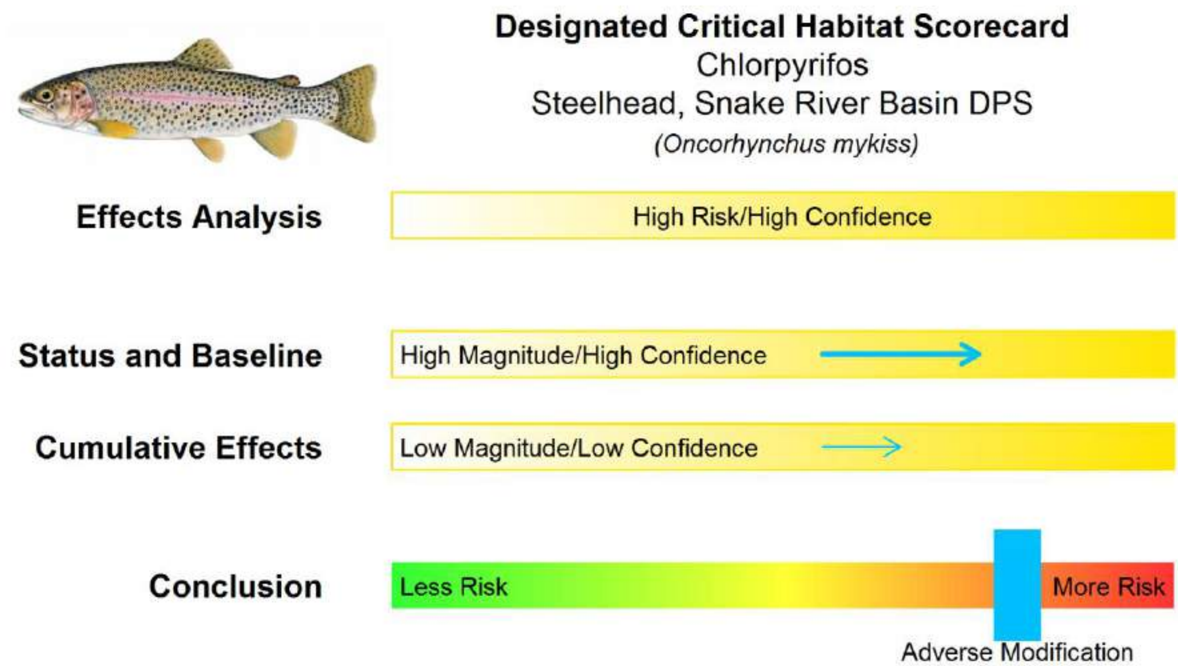

Figure 26. Designated Critical Habitat Scorecard; Steelhead, Snake River Basin DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Rearing PBFs are degraded by agricultural runoff, reduced invertebrate prey, loss of riparian vegetation, and elevated temperature
- Migration PBFs are degraded by several dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of assessed watersheds, 229 are of high and 41 are of medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 9,136,811 acres (over 52% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

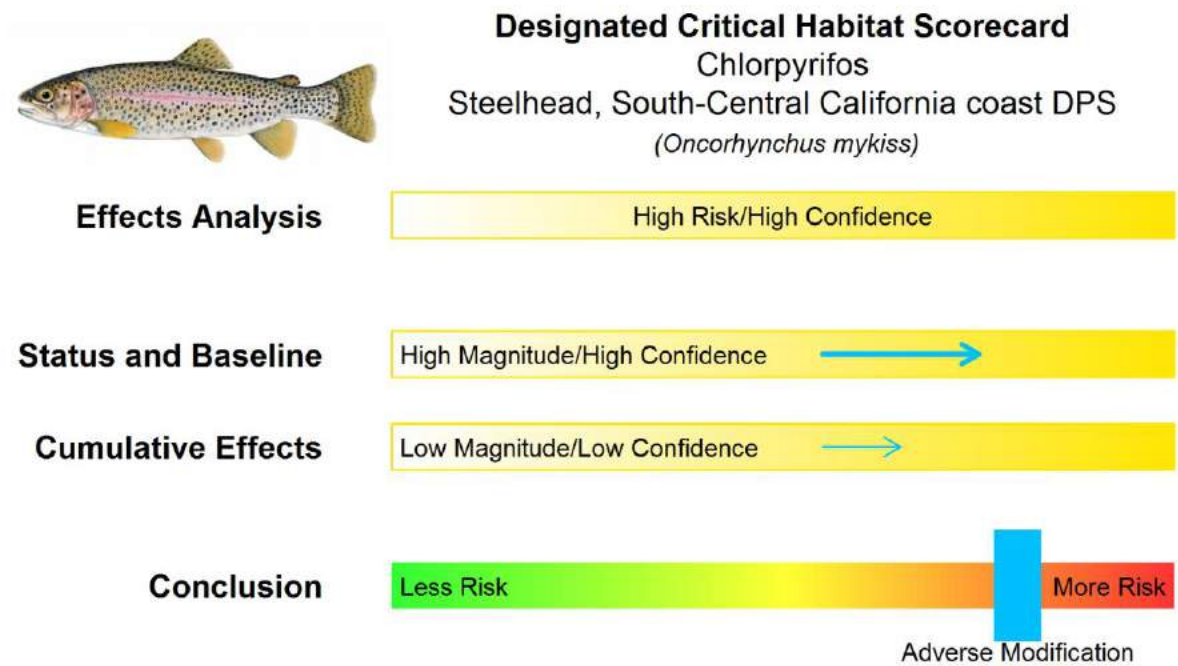

Figure 27. Designated Critical Habitat Scorecard; Steelhead, South-Central California coast DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing and migration PBFs are degraded by elevated temperatures and contaminants from urban and agricultural runoff
- Estuarine PBFs are degraded by altered habitat and contaminated runoff
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 29 occupied watersheds, 12 are of high and 11 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 1,409,107 acres (over 44% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

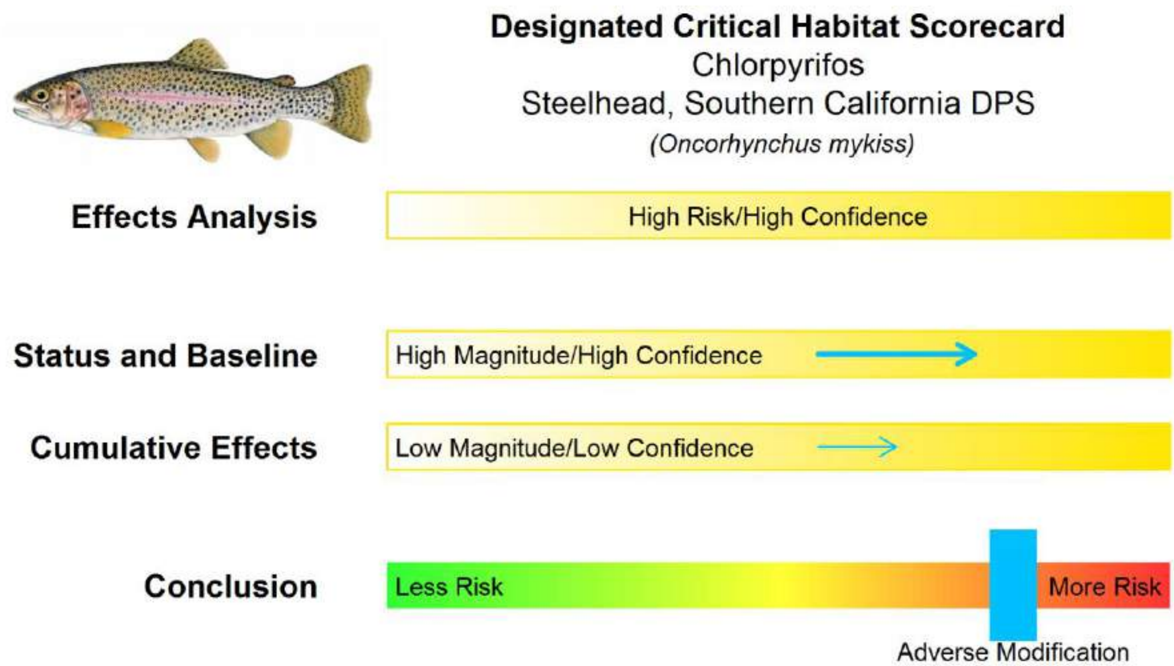

Figure 28. Designated Critical Habitat Scorecard; Steelhead, Southern California DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- All PBFs are degraded by pollutants in urban and agricultural runoff, elevated temperatures, erosion, and low water flows
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 29 freshwater and estuarine watersheds, 21 are of high and 5 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 765,006 acres (over 35% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

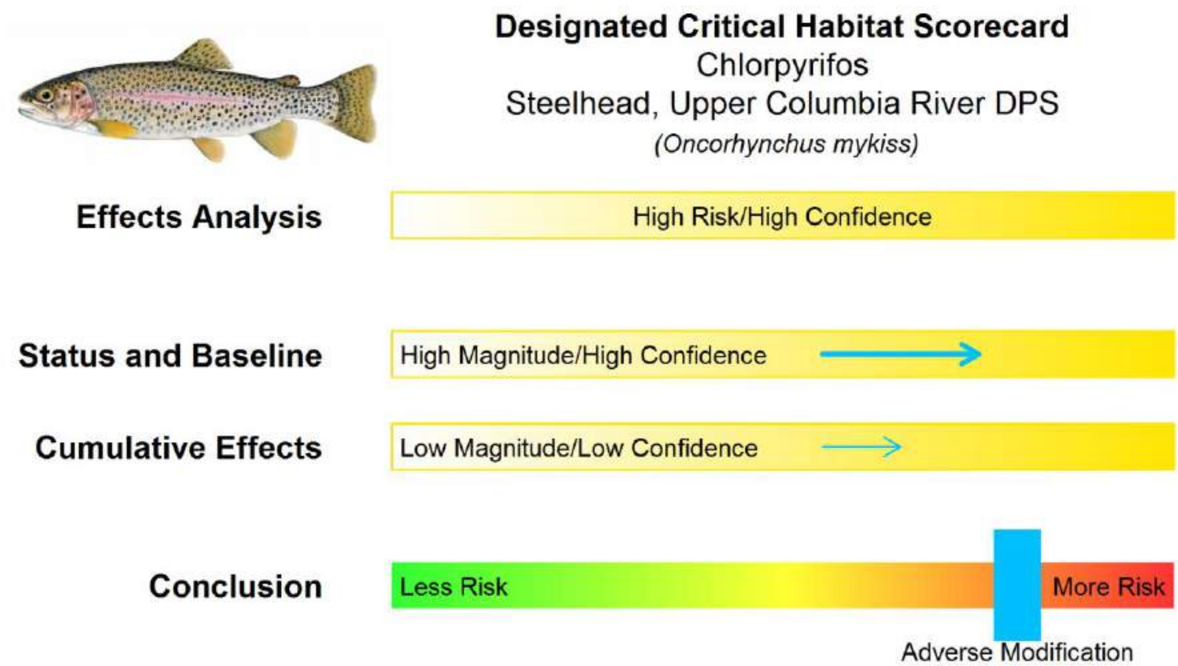

Figure 29. Designated Critical Habitat Scorecard; Steelhead, Upper Columbia River DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by agricultural runoff and lack of available prey
- Migration PBFs are degraded by several dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 41 occupied watersheds, 31 are of high and 7 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 2,017,023 acres (over 44% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

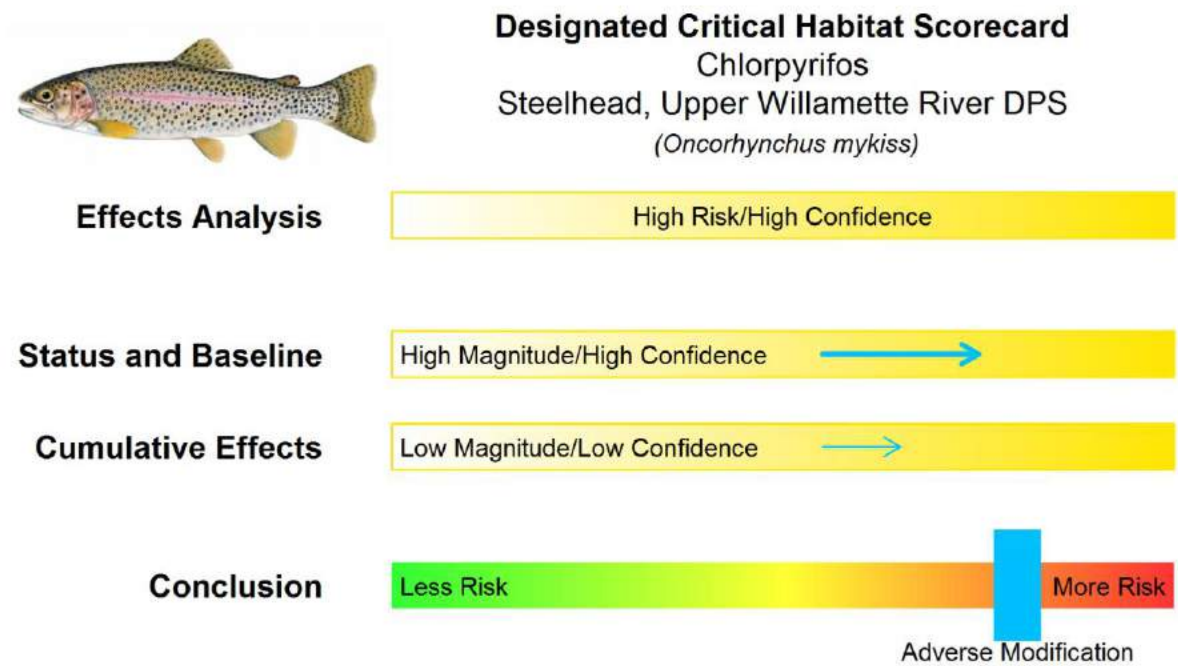

Figure 30. Designated Critical Habitat Scorecard; Steelhead, Upper Willamette River DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by agricultural runoff and lack of available prey
- Migration PBFs are degraded by dams and elevated temperatures
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of assessed watersheds, 14 are of high and 6 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Seventeen use site categories, totaling more than 1,685,690 acres (over 75% of critical habitat) currently overlap. Chlorpyrifos may be applied anywhere in this species' critical habitat for mosquito control and other wide area uses. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

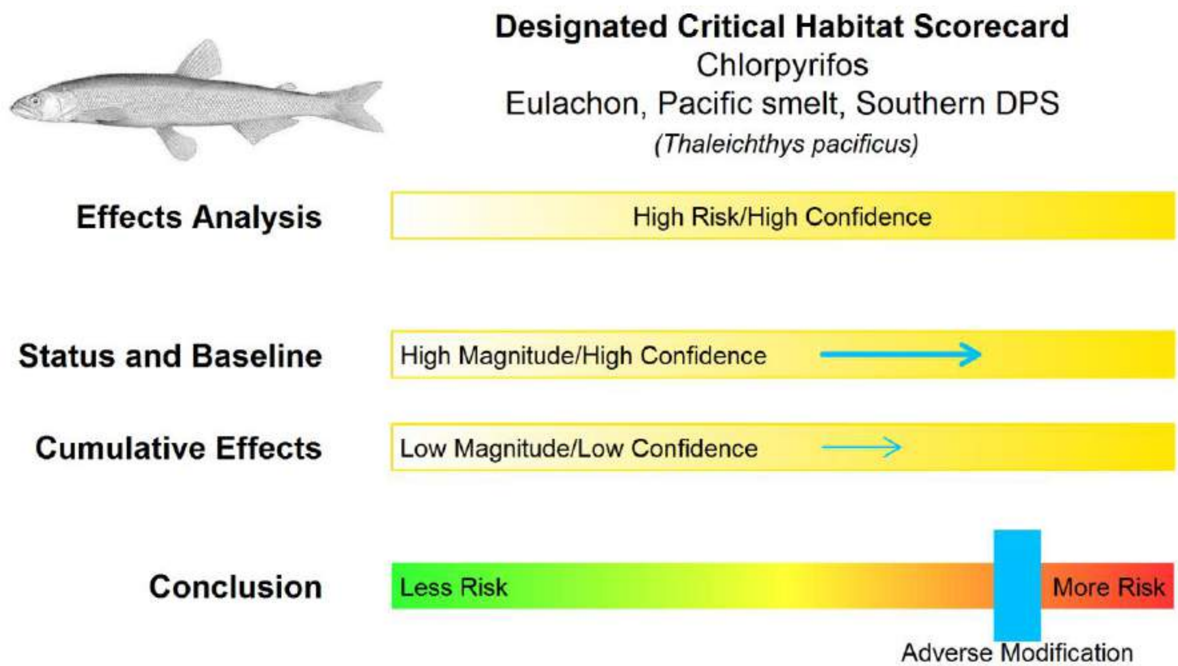

Figure 31. Designated Critical Habitat Scorecard; Eulachon, Pacific smelt, Southern DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, incubation, and rearing PBFs are degraded.
- Dams block flow and access to historical spawning grounds and are cause for degraded spawning substrates below.
- Elevated temperatures prevalent in freshwater habitats.
- Environmental mixtures anticipated in freshwater habitats may affect prey.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change a threat, particularly in eulachon's southern range where ocean warming may be most severe, altering prey, spawning, and rearing success.
- Anticipated hydrologic changes in freshwater areas may affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Chlorpyrifos may be applied anywhere in this species critical habitat for mosquito control and other wide area uses. Sixteen use site categories, totaling more than 420,163 acres (over 23 percent of acres) are currently present. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

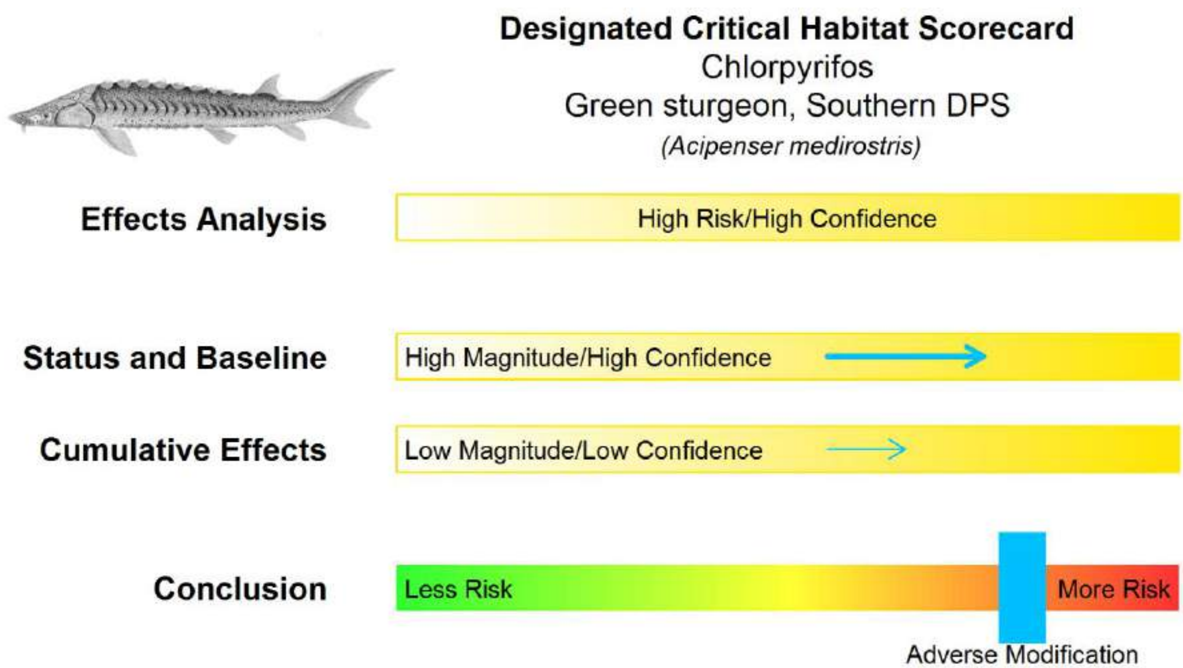

Figure 32. Designated Critical Habitat Scorecard; Green sturgeon, Southern DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Insufficient freshwater flow rates in spawning areas.
- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections in Sacramento River.
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Chlorpyrifos may be applied anywhere in this species critical habitat for mosquito control and other wide area uses. Seventeen use site categories, totaling more than 5,076,959 acres (over 49 percent of acres) are currently present. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

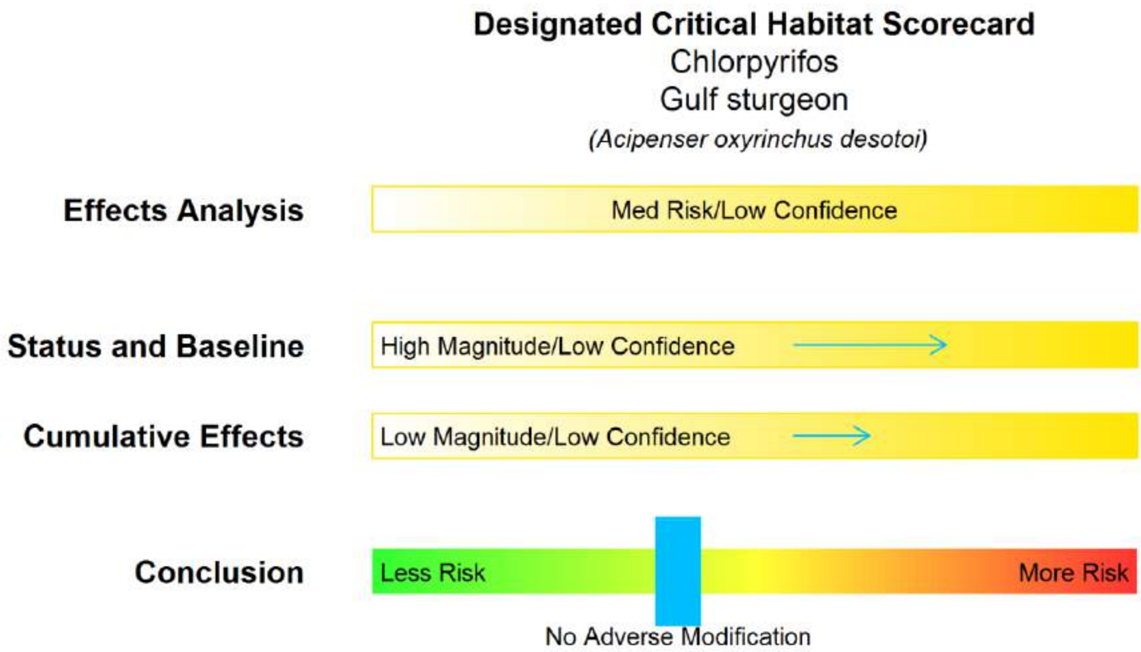

Figure 33. Designated Critical Habitat Scorecard; Gulf sturgeon; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted in their marine habitats.

Status and Baseline: Increased risk; High magnitude/Low confidence

- Construction of water control structures, such as dams and sills exacerbated habitat loss.
- Dredging.
- Groundwater extraction, irrigation, and altered flows.
- Poor water quality.
- Contaminants, primarily from industrial sources.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Global climate change may threaten PBFs.

Conclusion: We have low confidence in EECs predicted for the marine habitats. We find that the overall risk is medium and the confidence associated with that risk is low. We do not anticipate reductions in prey and degradation of water quality will reduce conservation values throughout the marine portion of this species designated critical habitat over the 15-year action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

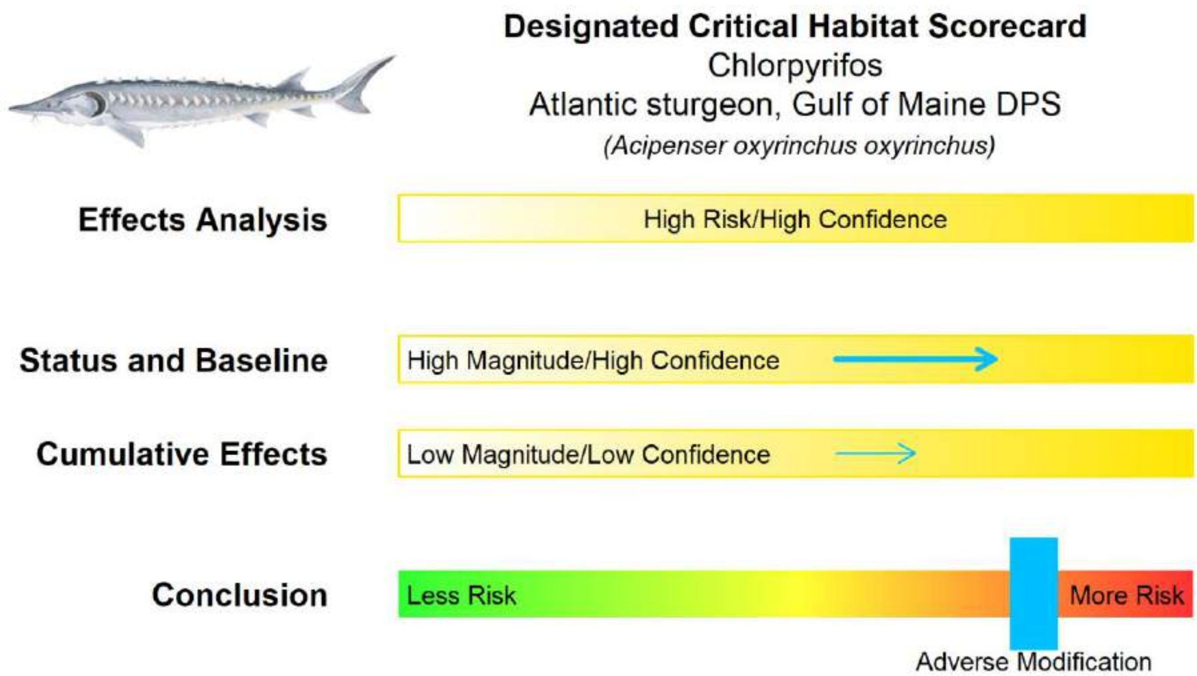

Figure 34. Designated Critical Habitat Scorecard; Atlantic sturgeon, Gulf of Maine DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Chlorpyrifos may be applied anywhere in this species critical habitat for mosquito control and other wide area uses. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

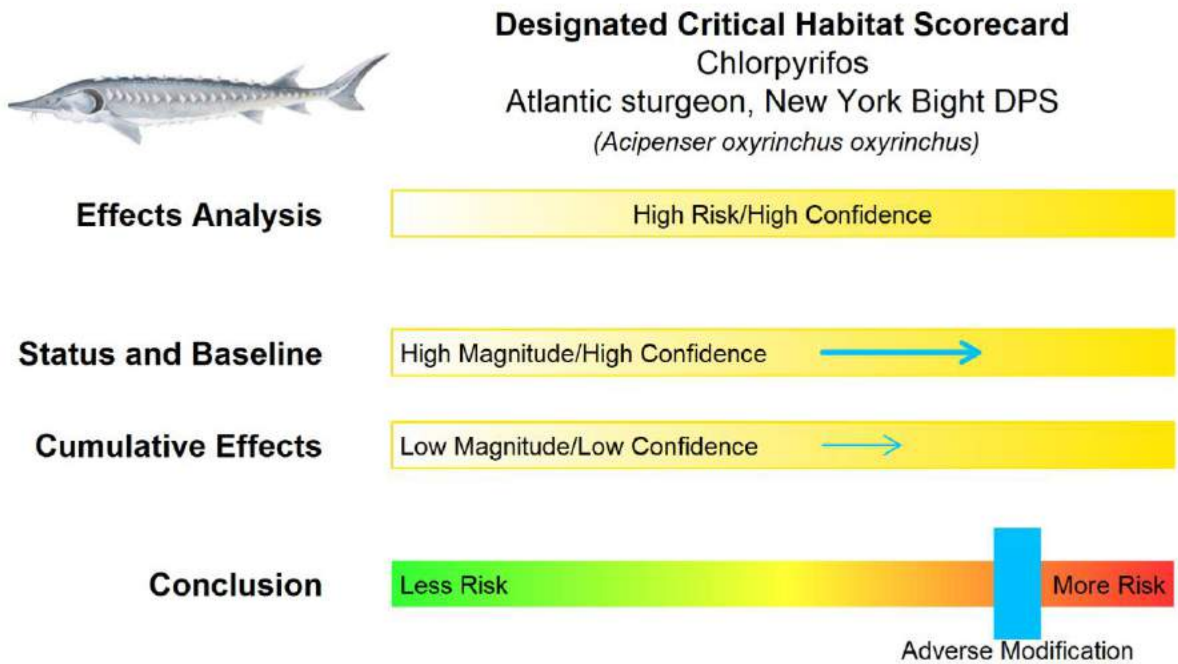

Figure 35. Designated Critical Habitat Scorecard; Atlantic sturgeon, New York Bight DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Chlorpyrifos may be applied anywhere in this species critical habitat for mosquito control and other wide area uses. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

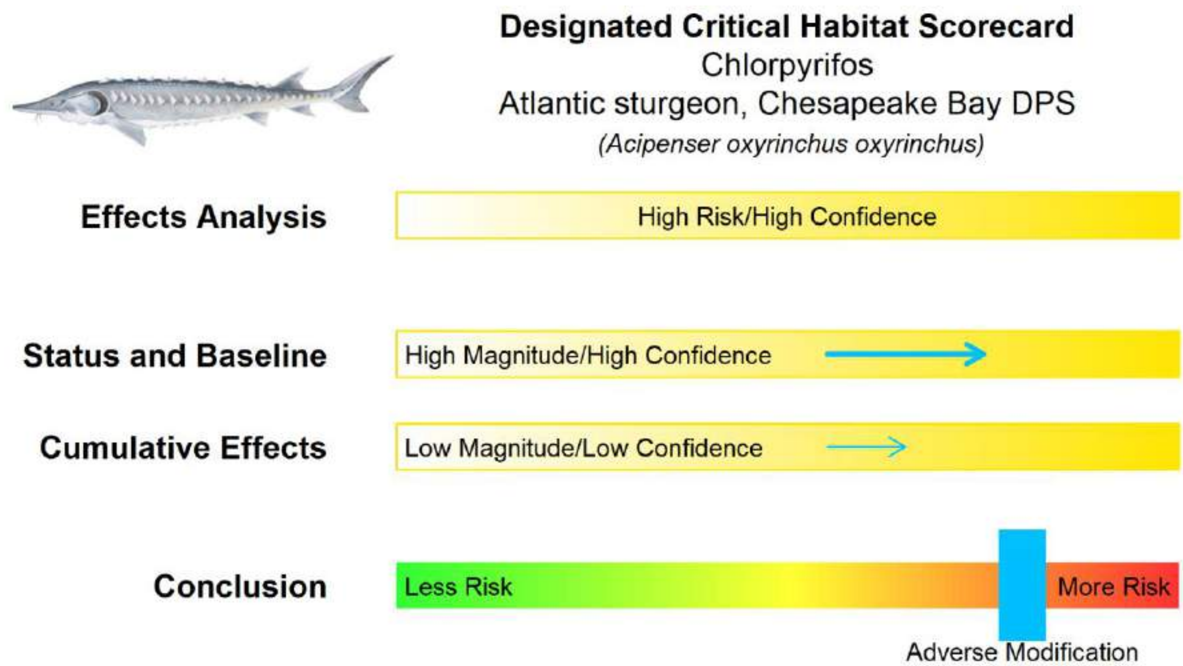

Figure 36. Designated Critical Habitat Scorecard; Atlantic sturgeon, Chesapeake Bay DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

<u>Conclusion:</u> We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Chlorpyrifos may be applied anywhere in this species critical habitat for mosquito control and other wide area uses. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

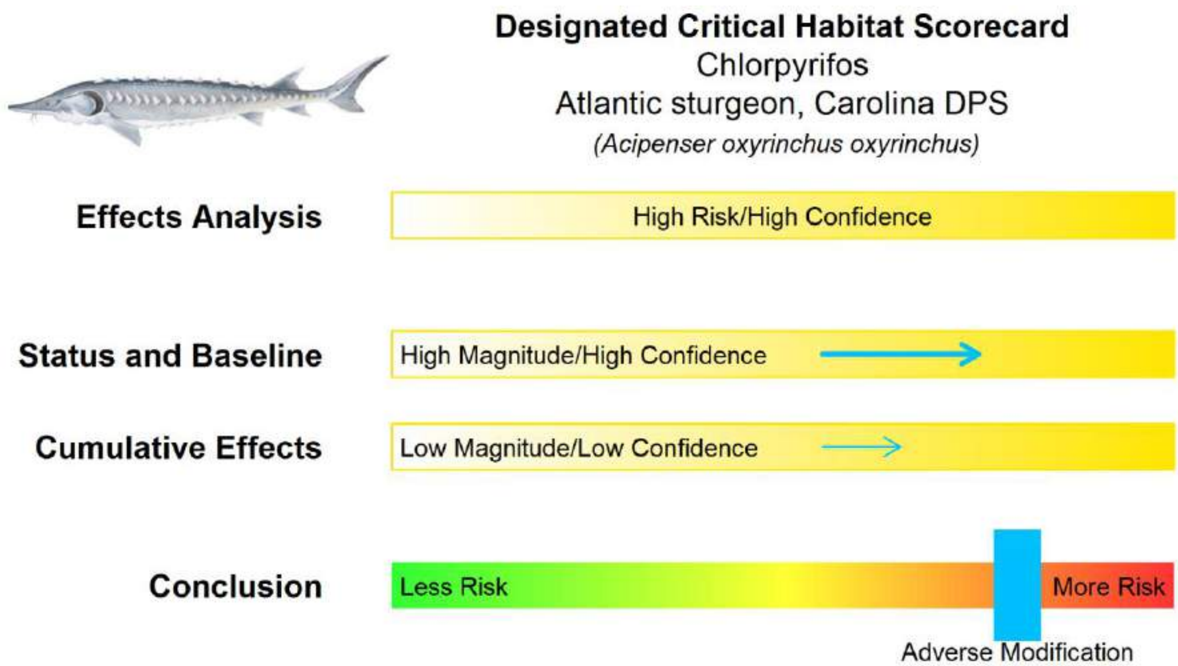

Figure 37. Designated Critical Habitat Scorecard; Atlantic sturgeon, Carolina DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Chlorpyrifos may be applied anywhere in this species critical habitat for mosquito control and other wide area uses. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

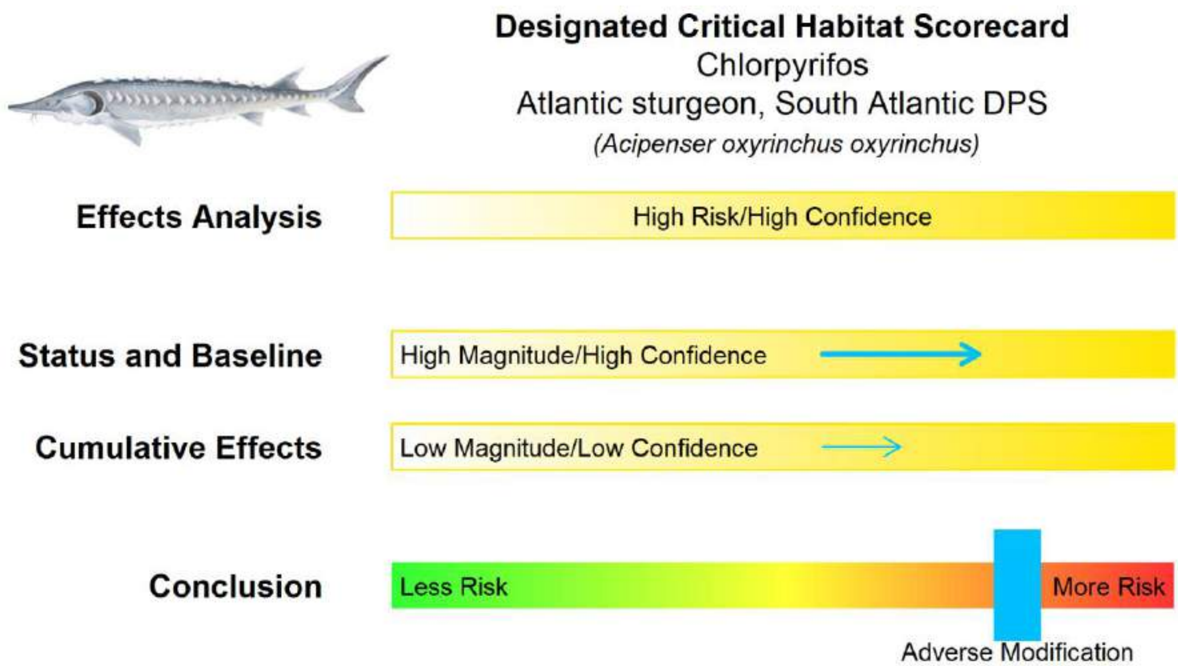

Figure 38. Designated Critical Habitat Scorecard; Atlantic sturgeon, South Carolina DPS; Chlorpyrifos

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

<u>Conclusion:</u> We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Chlorpyrifos may be applied anywhere in this species critical habitat for mosquito control and other wide area uses. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

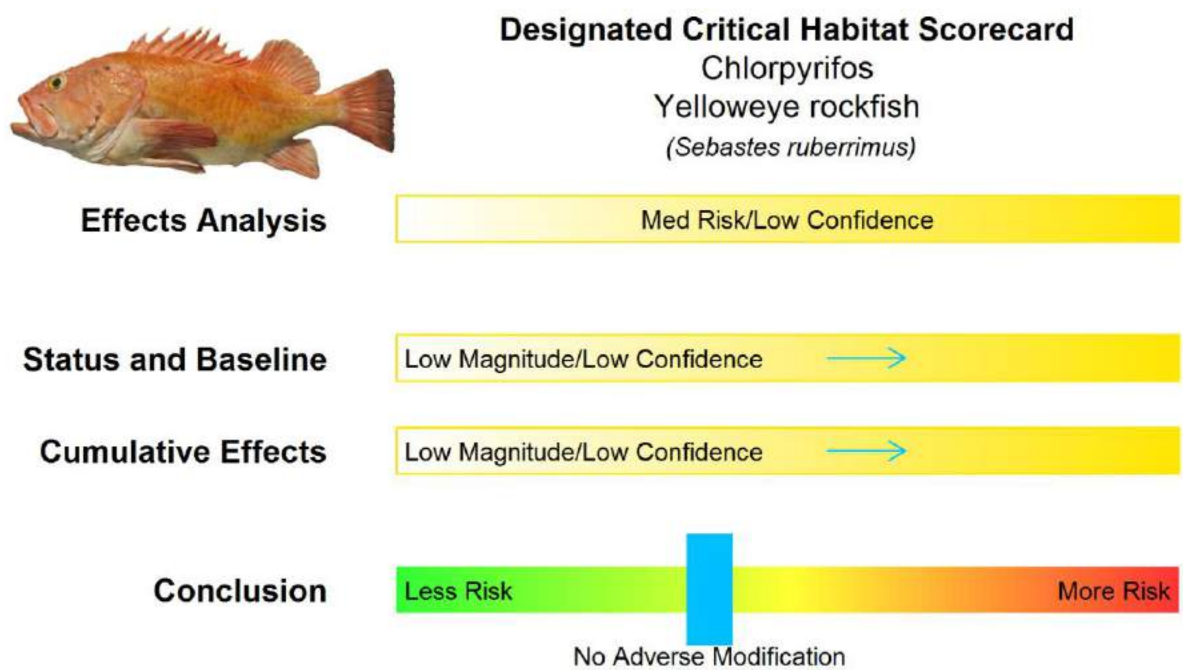

Figure 39. Designated Critical Habitat Scorecard; Yelloweye rockfish; Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted in their marine habitats.

<u>Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence</u>

- Adverse environmental factors have led to prey reductions and recruitment failures.

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Changes in ocean conditions brought about by climate change may threaten PBFs.

<u>Conclusion:</u> We have low confidence in EECs predicted for the marine habitats. We find that the overall risk is medium and the confidence associated with that risk is low. We do not anticipate reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

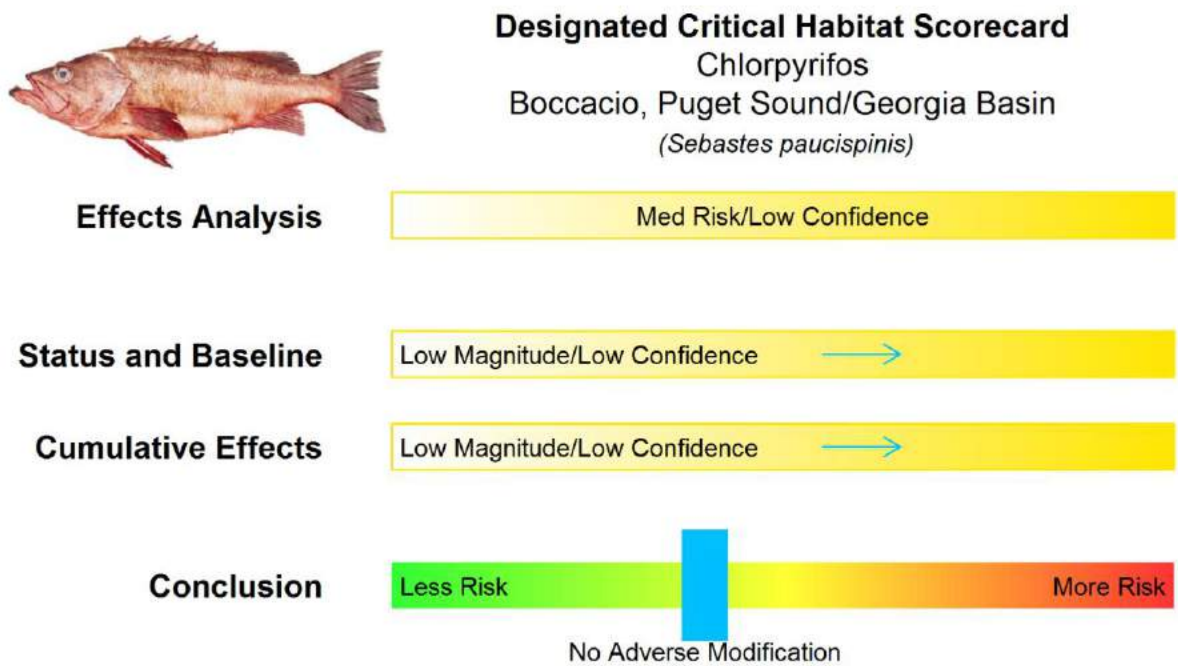

Figure 40. Designated Critical Habitat Scorecard; Boccacio, Puget Sound/Georgia Basin; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted in their marine habitats.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Adverse environmental factors have led to prey reductions and recruitment failures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.

Conclusion: We have low confidence in EECs predicted for the marine habitats. We find that the overall risk is medium and the confidence associated with that risk is low. We do not anticipate reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

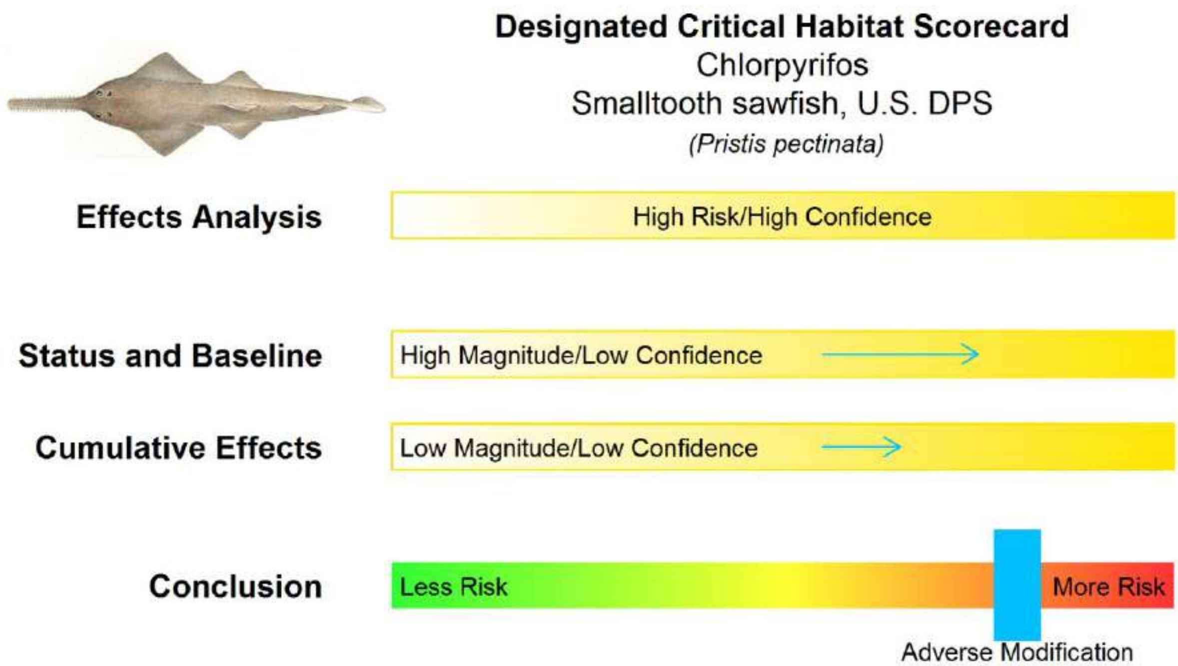

Figure 41. Designated Critical Habitat Scorecard; Smalltooth sawfish, U.S. DPS; Chlorpyrifos

Effects Analysis: High risk/High confidence

- Reductions in prey species are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/Low confidence

- Loss and degradation of female pupping sites and juvenile rearing habitats.
- Point and non-point contaminants.
- Marine Debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future losses in vegetated shallow water habitats from developmental pressures and global climate change may further threaten PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Chlorpyrifos may be applied anywhere in this species critical habitat for mosquito control and other wide area uses. Thirteen use site categories, totaling more than 543,533 acres (over 15 percent of acres) are currently present in land adjacent to designated critical habitat. Anticipated reductions in prey will reduce conservation values throughout designated critical habitat over the 15-year action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

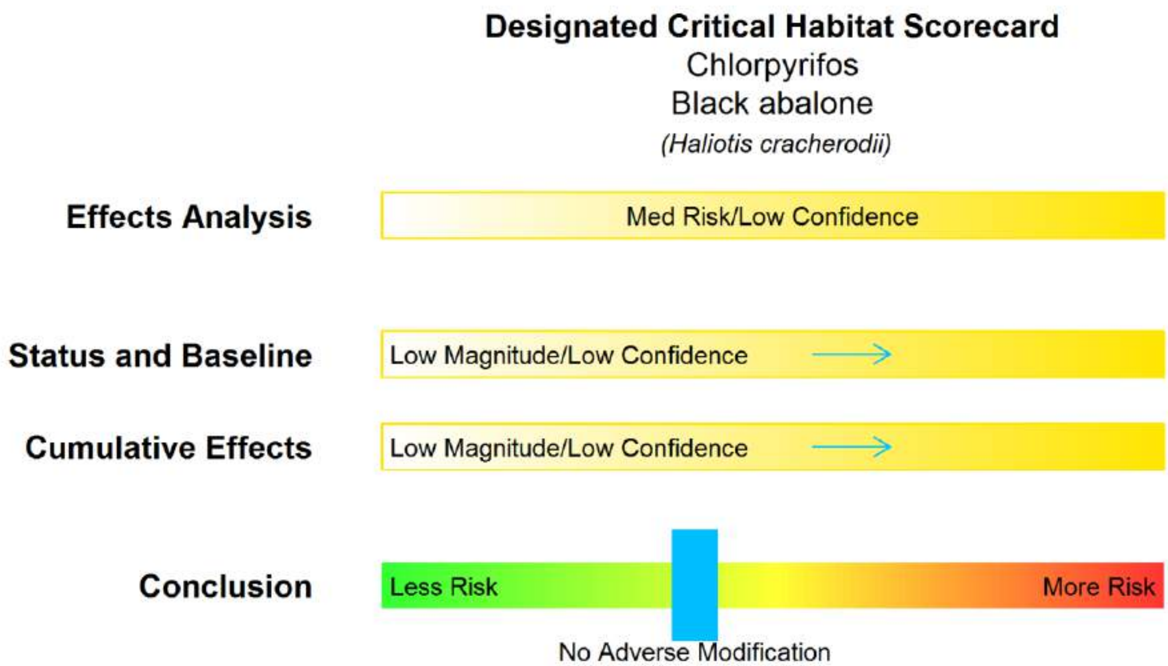

Figure 42. Designated Critical Habitat Scorecard; Black abalone; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey species and degradation of water quality in marine nearshore and inter-tidal habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Habitat destruction.
- Disease.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Developmental pressures could reduce available habitat and create competition for space with other marine invertebrates.
- Changes in ocean conditions (ocean acidification) may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical and biological features within nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat of Black Abalone. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

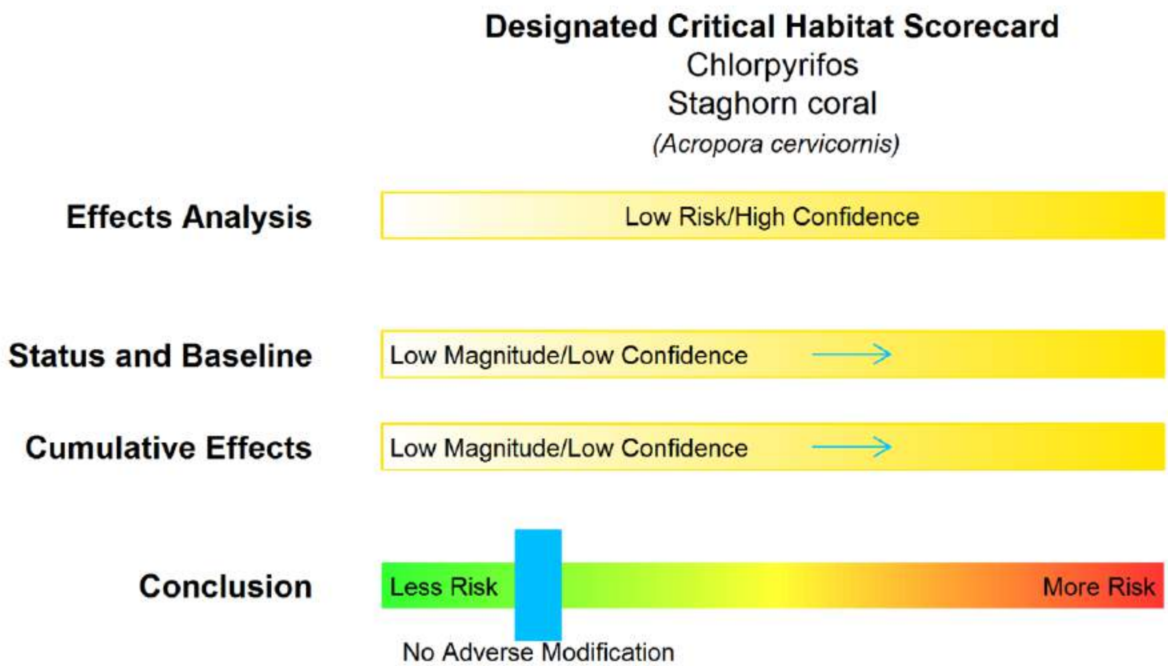

Figure 43. Designated Critical Habitat Scorecard; Staghorn coral; Chlorpyrifos

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in PBFs or reductions in the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted and PBFs identified.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease (white band).
- Habitat destruction.
- Bleaching (temperature variations).
- Sedimentation.
- Algal overgrowth (nutrification).

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions (e.g. increased water temperature and acidification) may threaten PBFs.

Conclusion: There are no physical and biological features identified in Staghorn Coral designated critical habitat that could be affected by the proposed action. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

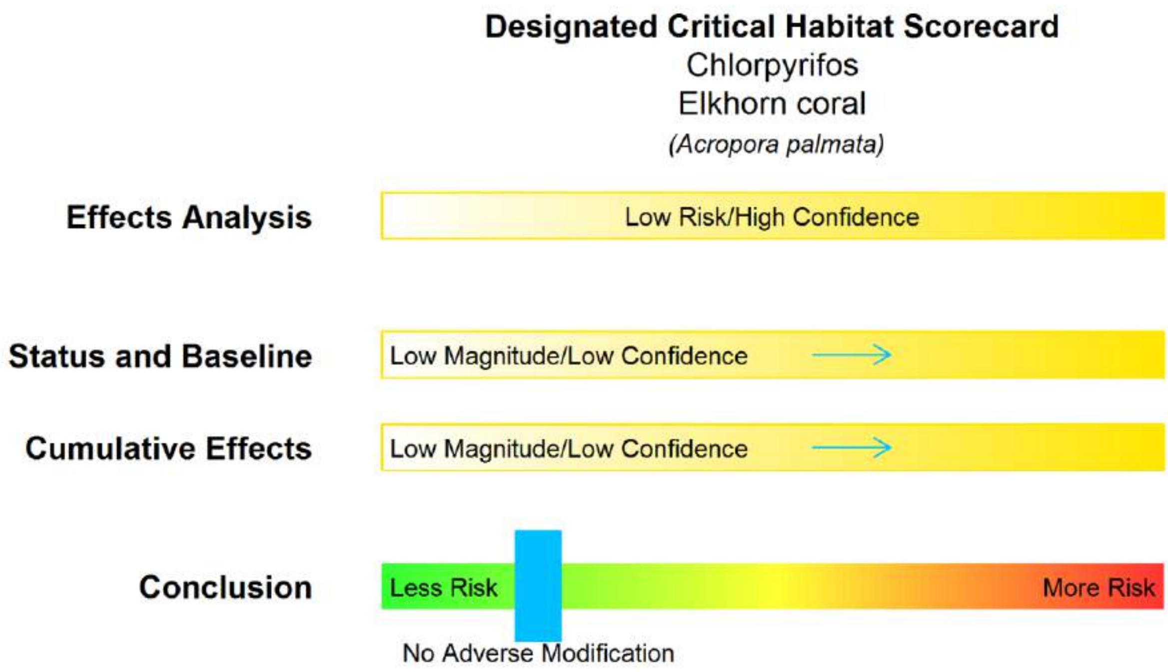

Figure 44. Designated Critical Habitat Scorecard; Elkhorn coral; Chlorpyrifos

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in PBFs or reductions in the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted and PBFs identified.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease (white band).
- Habitat destruction.
- Bleaching (temperature variations).
- Sedimentation.
- Algal overgrowth (nutrification).

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions (e.g. increased water temperature and acidification) brought about by climate change may threaten PBFs.

Conclusion: There are no physical and biological features identified in Staghorn Coral designated critical habitat that could be affected by the proposed action. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

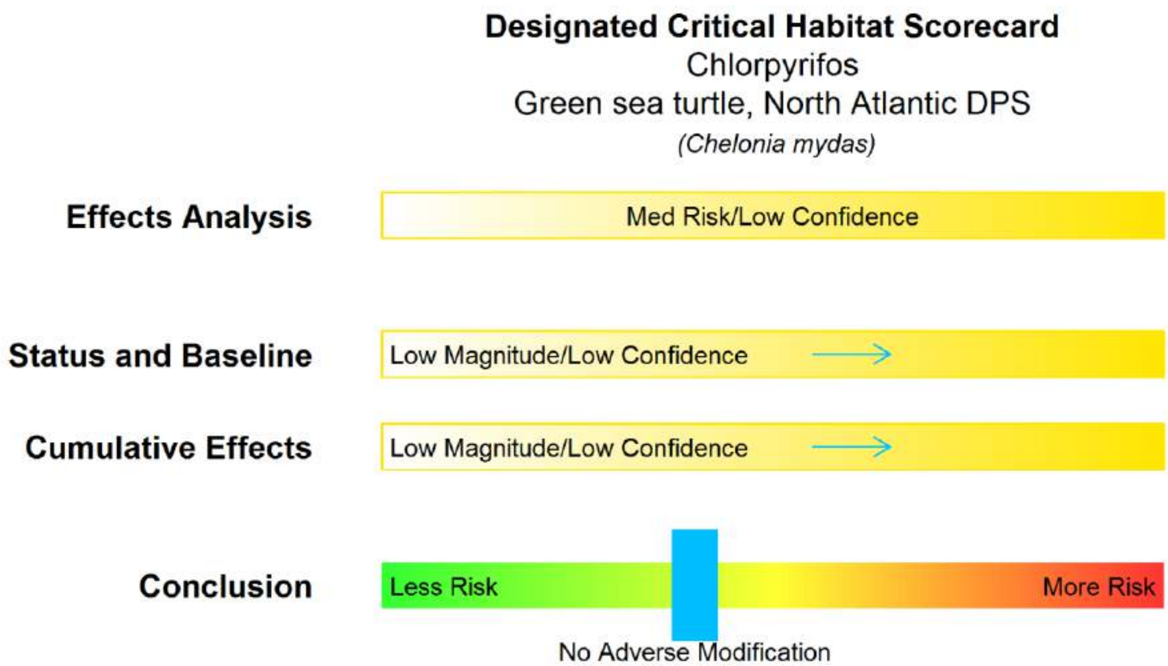

Figure 45. Designated Critical Habitat Scorecard; Green sea turtle, North Atlantic DPS; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in water quality in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease.
- Point and non-point pollution.
- Marine debris continues to build in critical habitat.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical and biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

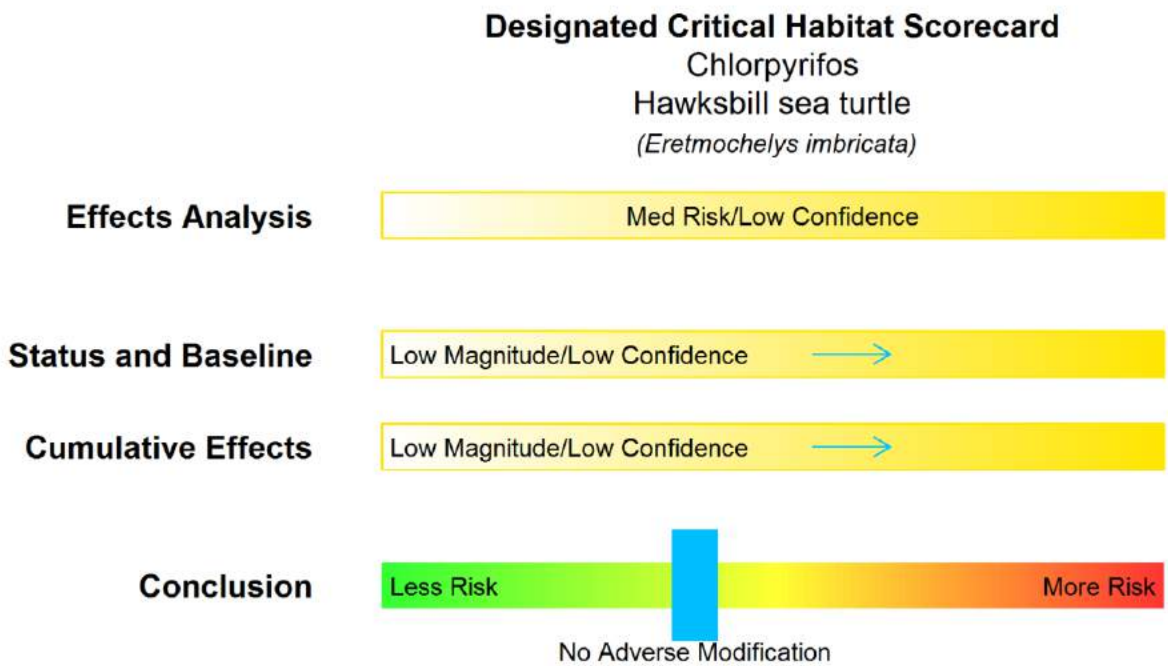

Figure 46. Designated Critical Habitat Scorecard; Hawksbill sea turtle; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in water quality in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease.
- Point and non-point pollution.
- Marine debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical and biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

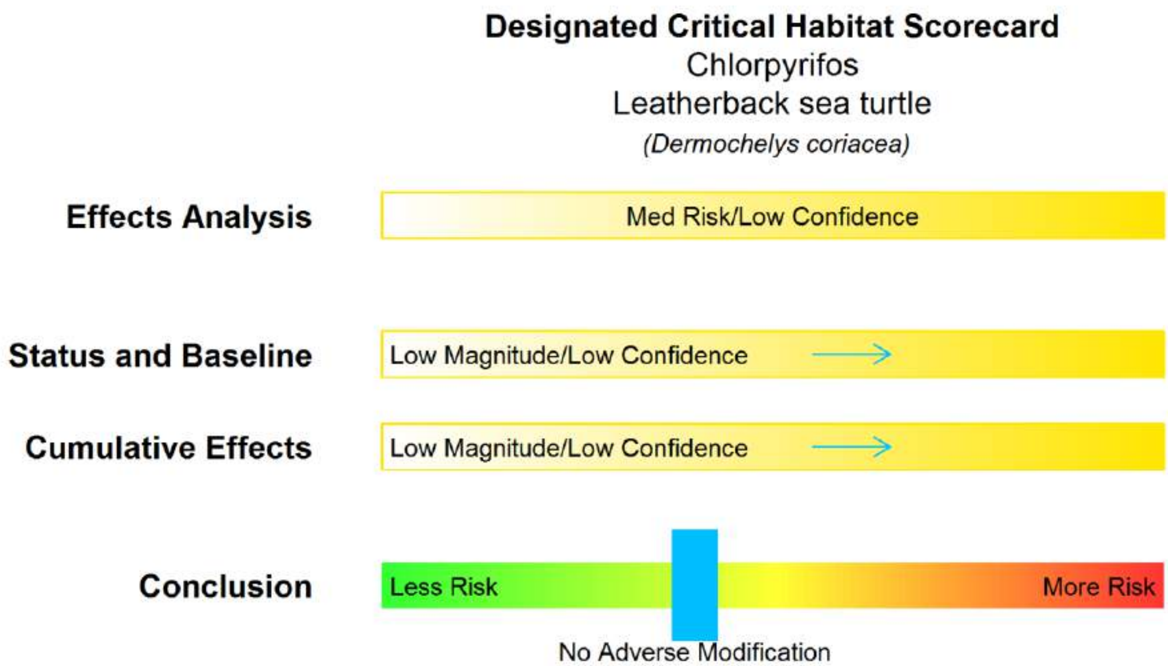

Figure 47. Designated Critical Habitat Scorecard; Leatherback sea turtle; Chlorpyrifos

<u>Effects Analysis: Medium risk/Low confidence</u>

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

<u>Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence</u>

- Disease.
- Point and non-point pollution.
- Marine debris.

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

<u>Conclusion:</u> The stressors of the action may negatively affect relevant physical and biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

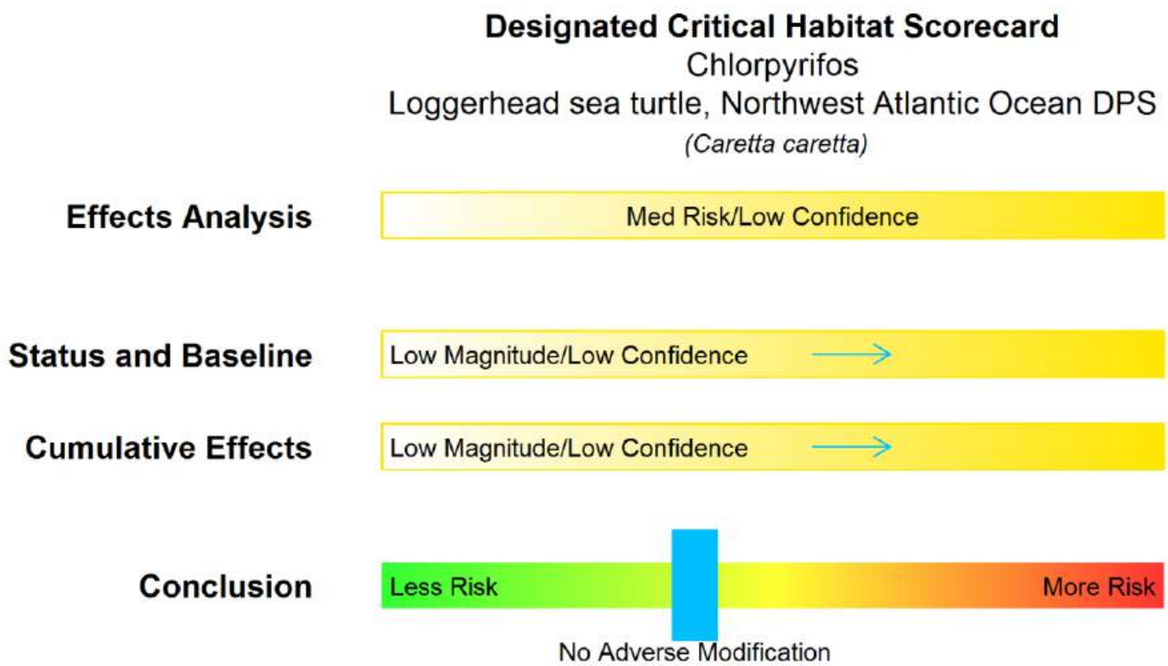

Figure 48. Designated Critical Habitat Scorecard; Loggerhead sea turtle, Northwest Atlantic Ocean DPS; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Point and non-point pollution.
- Marine debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical and biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

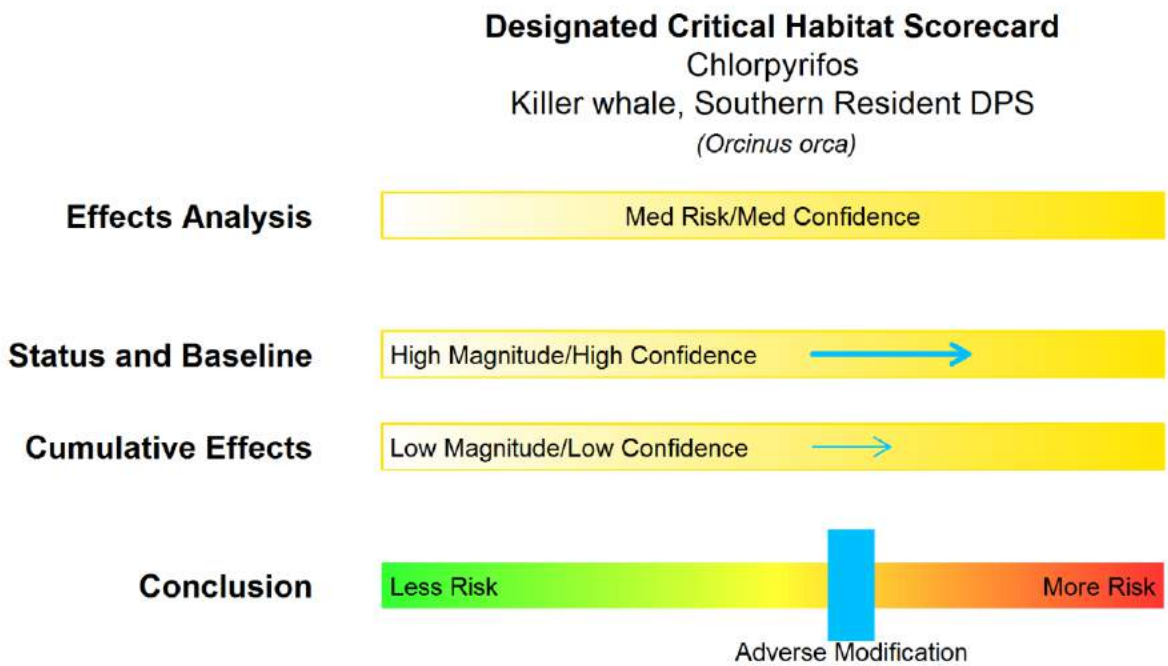

Figure 49. Designated Critical Habitat Scorecard; Killer whale, Southern Resident DPS; Chlorpyrifos

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey species availability are likely to reduce (indirectly) the overall conservation value of designated critical habitat.
- We find medium confidence of medium risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Depleted prey throughout designated critical habitat.
- Point and non-point contaminants.
- Noise disturbance.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Altered hydrology and affects to prey brought about by climate change.
- Increased stresses (e.g., temperature) to freshwater habitats critical to prey.

Conclusion: We do not anticipate stressors of the action will directly affect physical and biological features (PBFs). Reductions in suitable prey and degradation of water quality are unlikely throughout designated critical habitat of Southern Resident Killer Whale from this action. However, indirectly, prey species (Chinook salmon) will be adversely affected by exposures anticipated in their freshwater habitats. The likelihood and magnitude of toxic effects will reduce the overall conservation value of designated critical habitat by reducing the recruitment and availability of this important prey. We find that the overall risk is medium and the confidence associated with that risk is medium over the 15-year duration of the action.

Chlorpyrifos is likely to adversely modify designated critical habitat: Adverse Modification

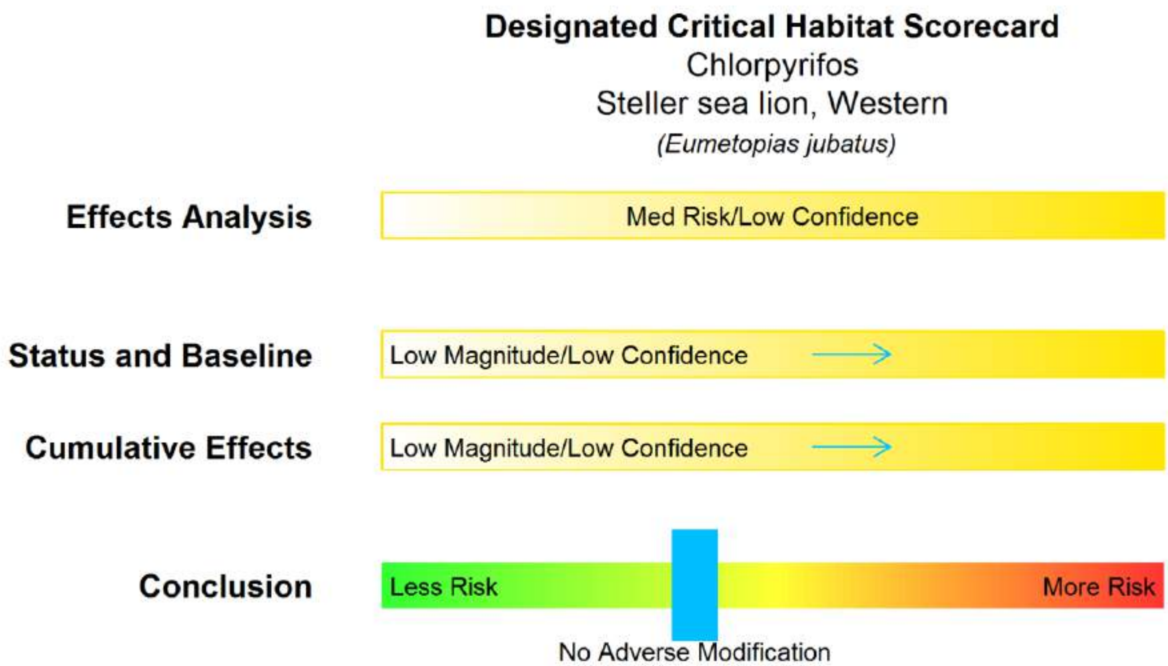

Figure 50. Designated Critical Habitat Scorecard; Steller sea lion, Western; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Point and non-point contaminants/pollution.
- Habitat degradation.
- Oil and gas exploration.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction/activities may threaten PBFs.

Conclusion: The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of Steller Sea Lion (Western DPS). However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

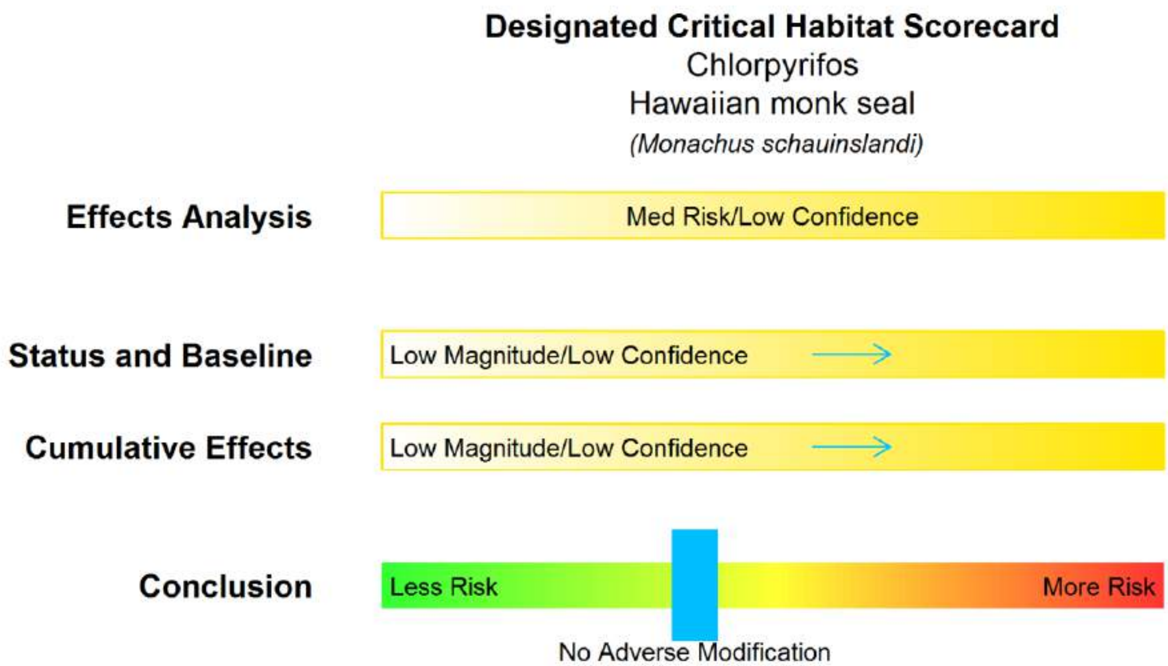

Figure 51. Designated Critical Habitat Scorecard; Hawaiian monk seal; Chlorpyrifos

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Limitations in food.
- Marine debris (entanglement).
- Habitat degradation.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction/activities may threaten PBFs.

Conclusion: The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of Hawaiian Monk Seal. However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of the marine portion of their designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

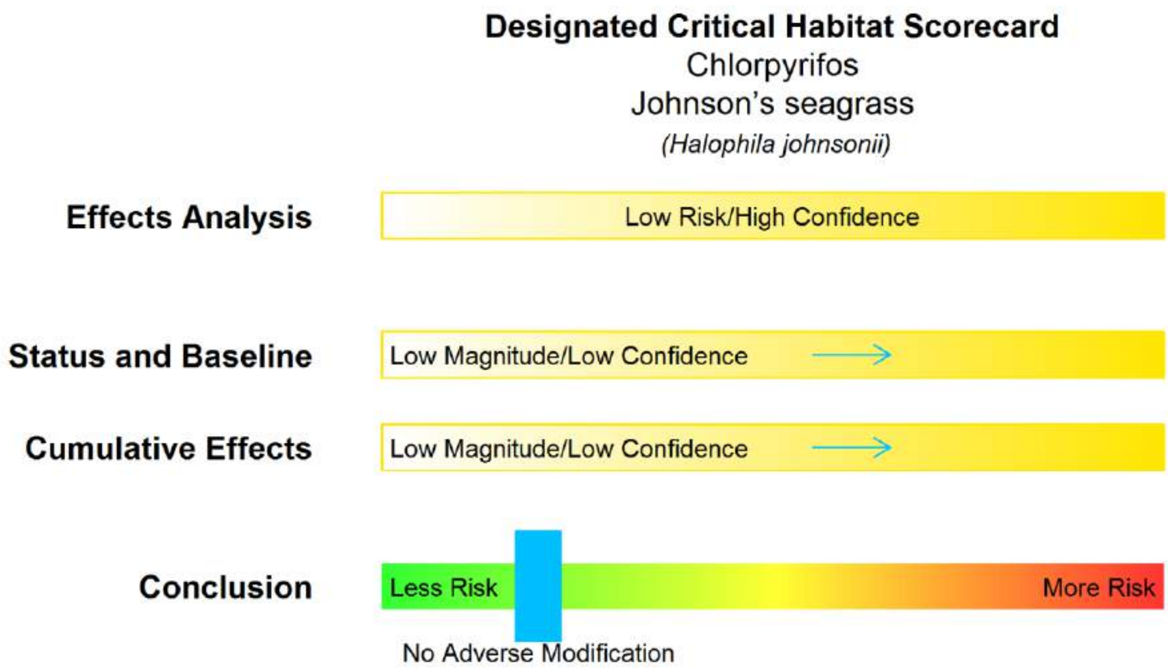

Figure 52. Designated Critical Habitat Scorecard; Johnson's seagrass; Chlorpyrifos

<u>Effects Analysis: Low risk/High confidence</u>

- We do not anticipate reductions in PBFs or reductions in the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted and PBFs identified.

<u>Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence</u>

- Degraded water quality.
- Habitat destruction
- Siltation due to land-use practices.
- Algal overgrowth (nutrification).

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Changes in ocean conditions brought about by climate change may threaten PBFs.

<u>Conclusion:</u> Water quality is a physical and biological features identified in Johnson's seagrass designated critical habitat. However, we do not anticipate exposures from the stressors of the action to be sufficient to reduce conservation values of this PBF. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Chlorpyrifos is not likely to adversely modify designated critical habitat: No Adverse Modification

CHAPTER 23

INTEGRATION AND SYNTHESIS FOR DESIGNATED CRITICAL HABITAT

DIAZINON

TABLE OF CONTENTS

23 Diazinon

23.1 Introduction

The integration and synthesis section is the final step in our assessment of the risk posed to species and critical habitat as a result of implementing the proposed action. In this section, we add the effects of the action to the environmental baseline and the cumulative effects to formulate the agency's biological opinion as to whether the proposed action is likely to: (1) reduce appreciably the likelihood of both the survival and recovery of an Endangered Species Act (ESA)-listed species in the wild by reducing its numbers, reproduction, or distribution; or (2) appreciably diminish the value of designated critical habitat for the conservation of an ESA-listed species. These assessments are made in full consideration of the status of the species.

We treat the information from the status of the species, environmental baseline, and cumulative effects, as "risk modifiers," in that the effects described in the effects analysis section may be modified by the condition of the species; the condition of environmental baseline, and the anticipated cumulative effects. The key questions addressed include:

- Status of Designated Critical Habitat:
    - Are the PBFs impaired or degraded?
- Environmental Baseline:
    - Are freshwater temperatures elevated?
    - Are pesticide environmental mixtures present, or anticipated based on current land use?
- Cumulative Effects:
    - Will future temperatures impair species aquatic habitats?
    - Will future hydrologic flows impair freshwater species habitats?
    - How might changes in ocean conditions affect the species habitat?

As detailed in the Environmental Baseline and Cumulative Effects chapters, adverse toxic responses to exposures to these OP pesticides are heightened with increases in temperature. In addition, exposures to other pesticides in the environment can cause additive or synergistic responses when simultaneously exposed to any of these OPs. Altered hydraulic flows can cause migratory blockages. Lower hydraulic flows can also result in increases in water temperatures and reductions in dissolved oxygen levels. These conditions can put stress on aquatic species and increases toxic responses when exposed to these pesticides.

Once each of the above sections is evaluated i.e., questions answered, the effects of the action and the risk modifiers are depicted graphically on a "scorecard." First, we assign a magnitude of influence (small or large) indicated graphically with one of two lengths of arrows. The shorter of the two arrows indicates a low magnitude, while the longer of the two arrows indicates a high magnitude as a risk modifier. The direction an arrow is pointed indicates the directionality of the risk modifier. For example, an environmental baseline arrow pointing towards more risk may indicate that environmental mixtures and elevated temperatures occur in the Environmental Baseline, which further stresses the species in question. We also assign a level of confidence in our selection of the small and large magnitude, indicated by a bold arrow (high confidence) or an un-bolded arrow (low confidence). The final arrow representing the influence on risk is graphically depicted on each of the designated critical habitat scorecards.

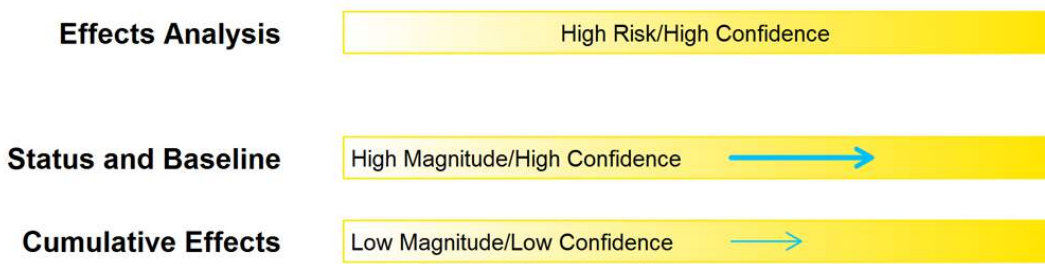

Figure 1. Example of arrows to represent direction, magnitude, and confidence of risk modifiers

Conclusion Section:
We combine the effects analysis conducted in chapters 15 – 17 with the baseline status of the species habitat, and cumulative effects to determine whether the action could reasonably be expected to appreciably diminish the conservation value of designated critical habitat. We state our conclusion as to whether the action is likely to destroy or adversely modify each of the species designated critical habitats.

A scorecard is generated for each species designated critical habitat. The effects of the proposed action is considered based on magnitude and confidence of the three arrows. Next, an adverse modification or no adverse modification vertical blue bar is placed on the horizontal risk bar i.e., the colored bar beginning with green (less risk) to red (more risk) (***Figure 2***) to depict our conclusion.

Figure 2: Example conclusion graphic

23.2 Designated Critical Habitat Scorecards (Diazinon)

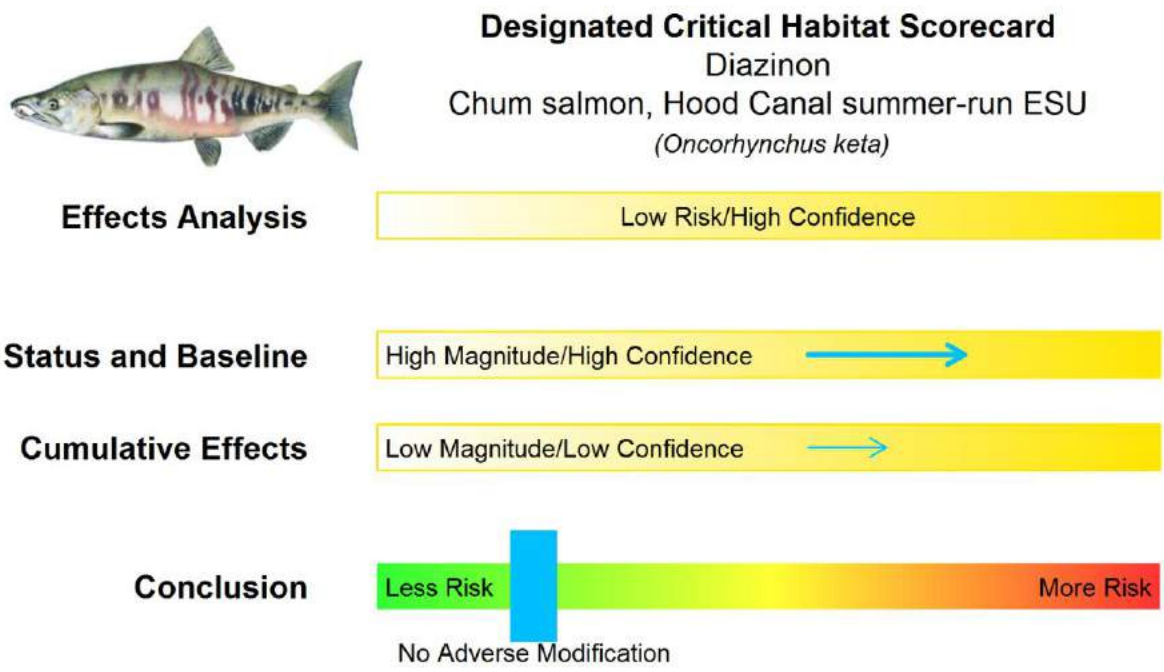

Figure 3. Designated Critical Habitat Scorecard; Chum salmon, Hood Canal summer-run Evolutionarily Significant Unit (ESU); Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded
- Migration and rearing PBFs are impaired by loss of floodplain habitat necessary for juvenile growth and development
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- All 12 watersheds of high or medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

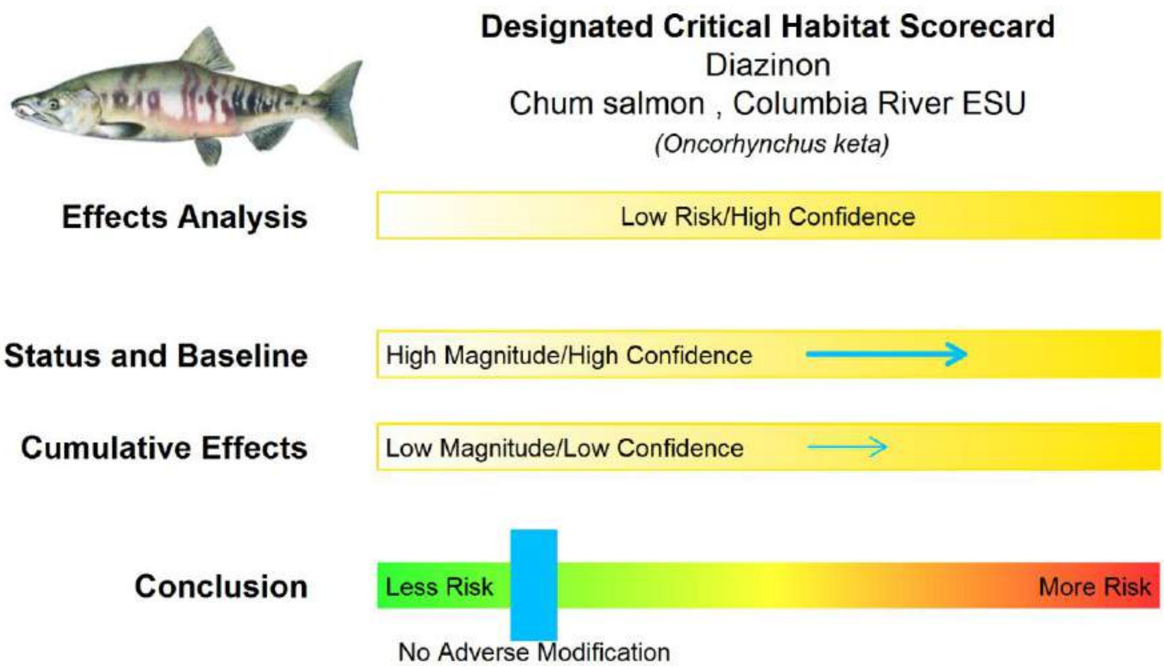

Figure 4. Designated Critical Habitat Scorecard; Chum salmon, Columbia River ESU; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Rearing PBFs (water quality and cover) are degraded
- Migration PBFs significantly impacted by dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- All 19 watersheds of high or medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

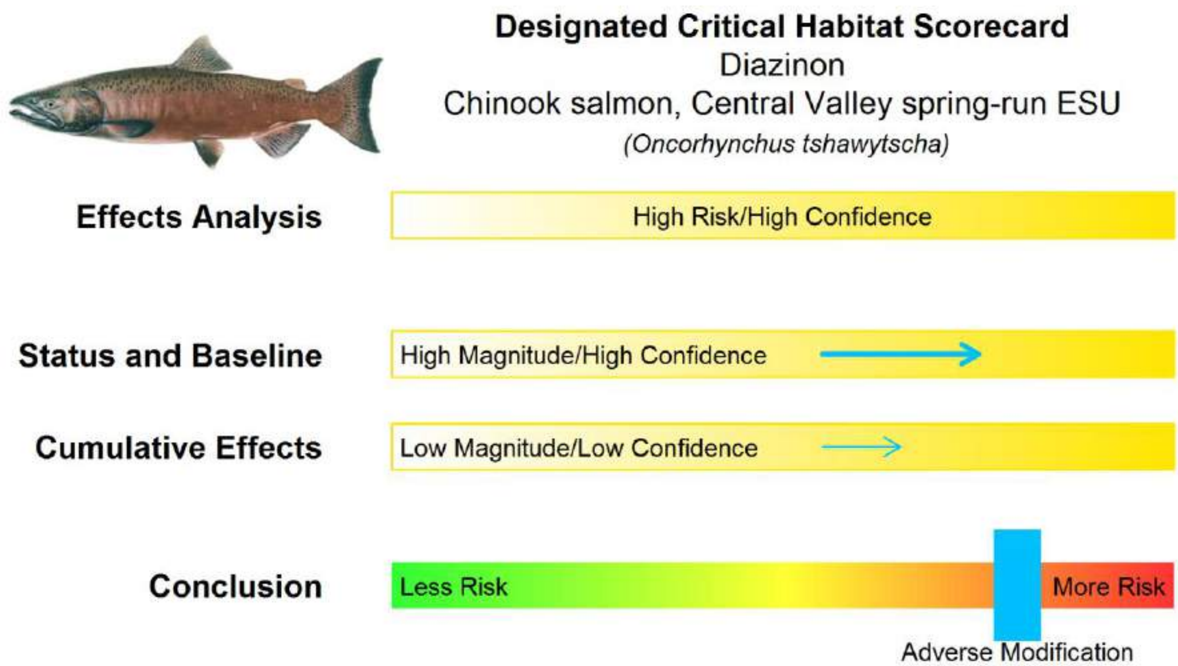

Figure 5. Designated Critical Habitat Scorecard; Chinook salmon, Central Valley spring-run ESU; Diazinon

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by elevated temperatures, lost access to historic spawning sites, and loss of floodplain habitat
- Migration PBFs degraded by loss of cover and water diversions
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 38 watersheds, 28 are of high and 3 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 332,480 acres (over 10% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

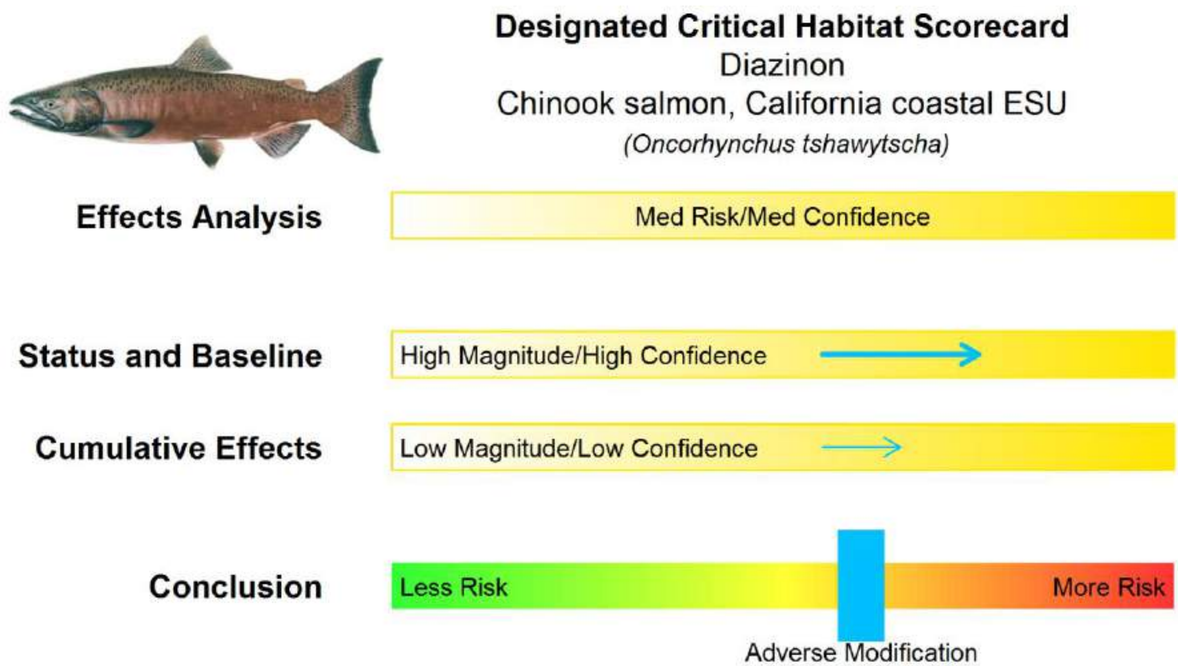

Figure 6. Designated Critical Habitat Scorecard; Chinook salmon, California coastal ESU; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning PBFs are degraded by timber harvest
- Rearing and migration PBFs impacted by dams and invasive species.
- Estuarine PBFs degraded by water quality and saltwater mixing
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 45 watersheds, 27 are of high and 10 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 46,855 acres (over 1% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

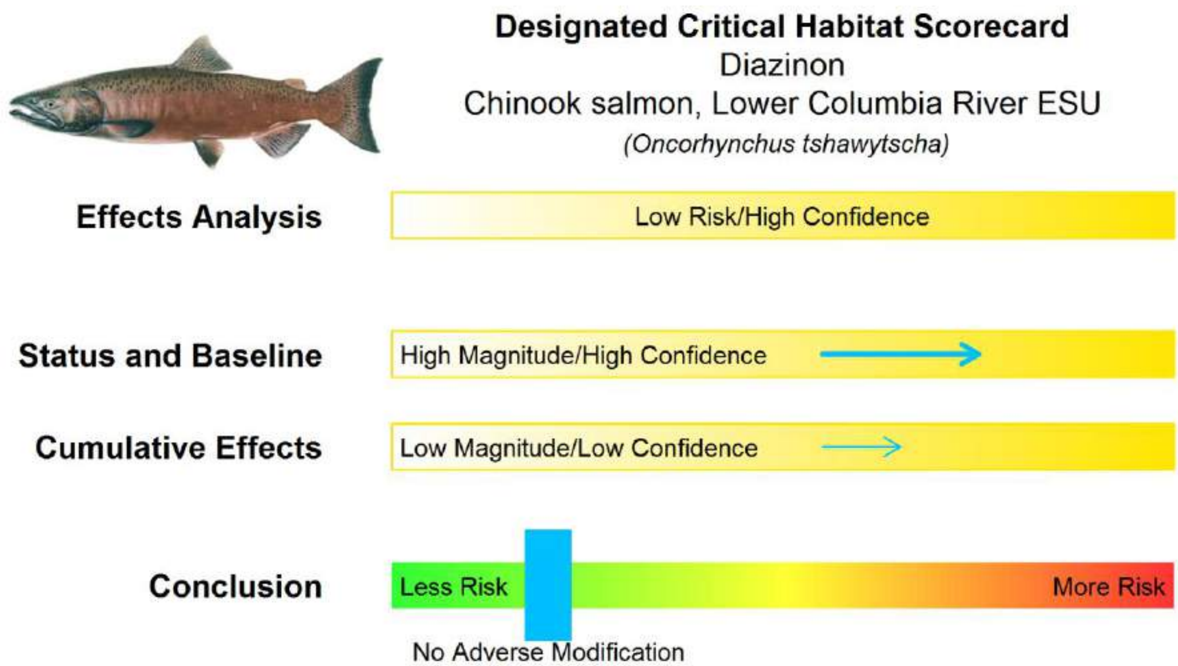

Figure 7. Designated Critical Habitat Scorecard; Chinook salmon, Lower Columbia River ESU; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by timber harvest, agriculture, urbanization, loss of floodplain habitat, and reduced natural cover
- Migration PBFs impacted by dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of occupied watersheds, 31 are of high and 13 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

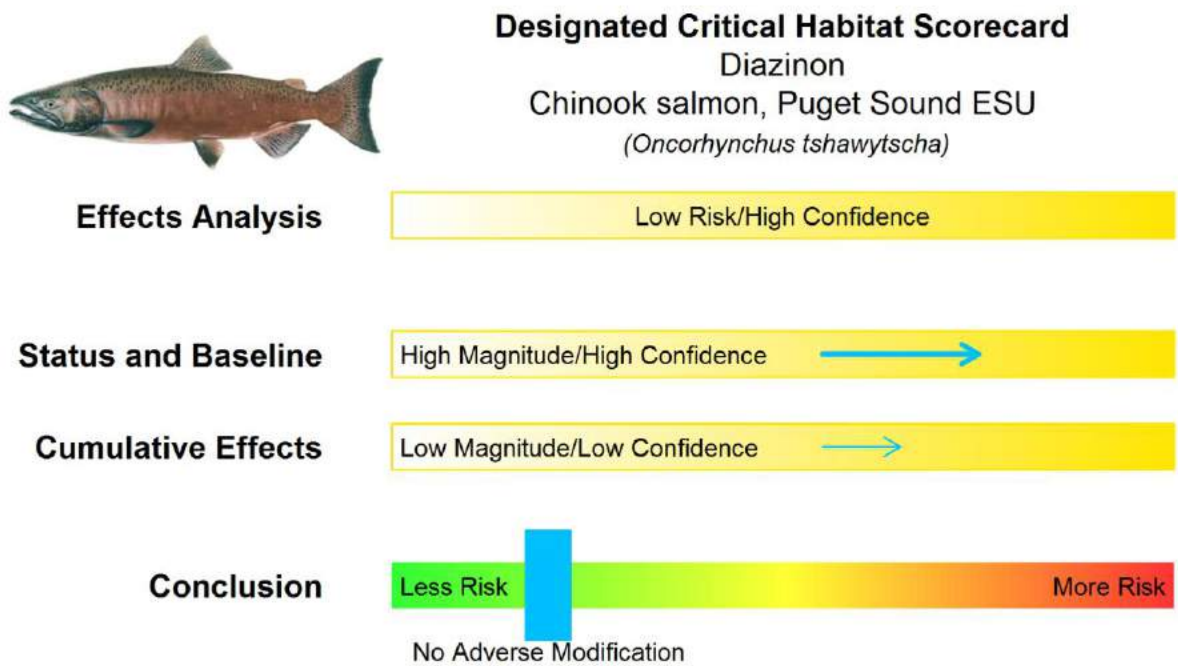

Figure 8. Designated Critical Habitat Scorecard; Chinook salmon, Puget Sound ESU; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, rearing and migration PBFs are degraded by forestry, agriculture, urbanization, and loss of habitat
- Estuarine PBFs degraded by water quality, altered salinity, and lack of natural cover
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 61 watersheds, 40 are of high and 9 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

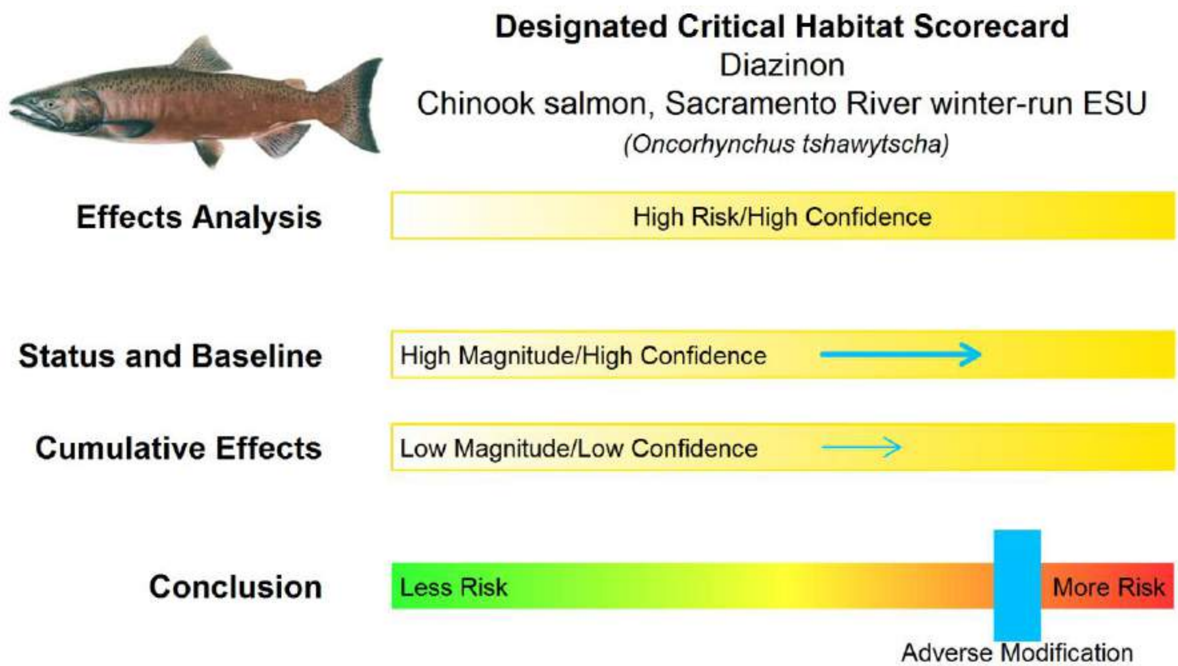

Figure 9. Designated Critical Habitat Scorecard; Chinook salmon, Sacramento River winter-run ESU; Diazinon

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by elevated temperatures and loss of habitat
- Migration PBFs degraded by lack of natural cover and water diversions
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire Sacramento river and delta are considered of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 106,617 acres (over 8% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

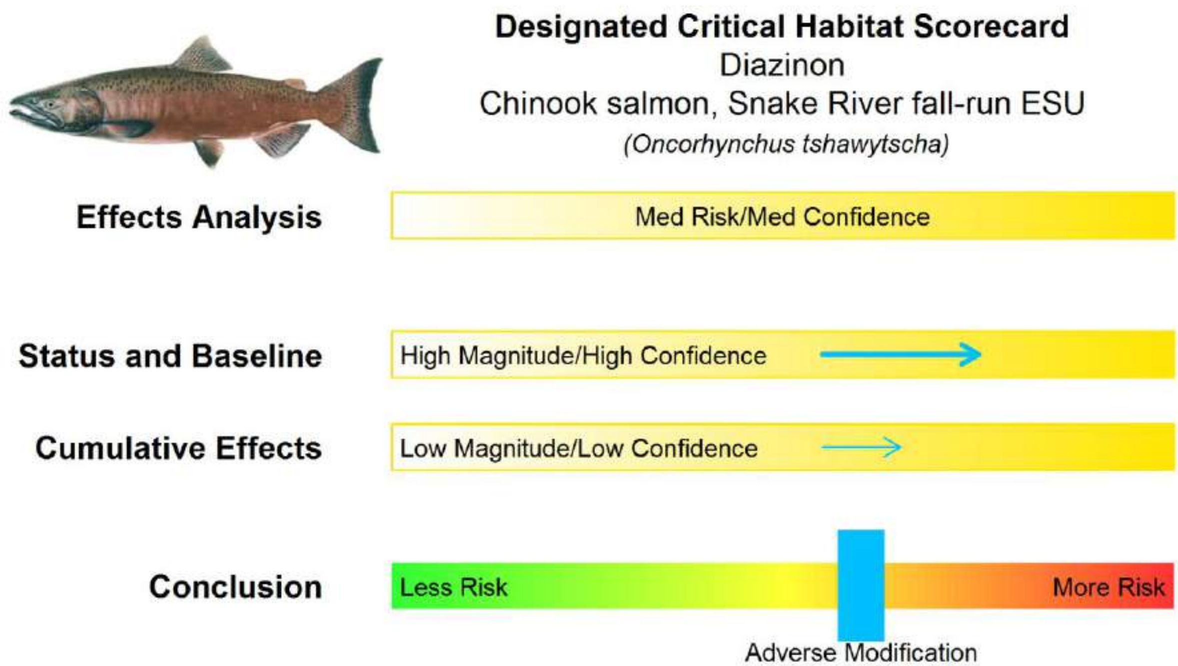

Figure 10. Designated Critical Habitat Scorecard; Chinook salmon, Snake River fall-run ESU; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, rearing and migration PBFs are degraded by loss of habitat, impaired stream flows, barriers to fish passage, and poor water quality
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire river corridor is considered of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 251,769 acres (over 4% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

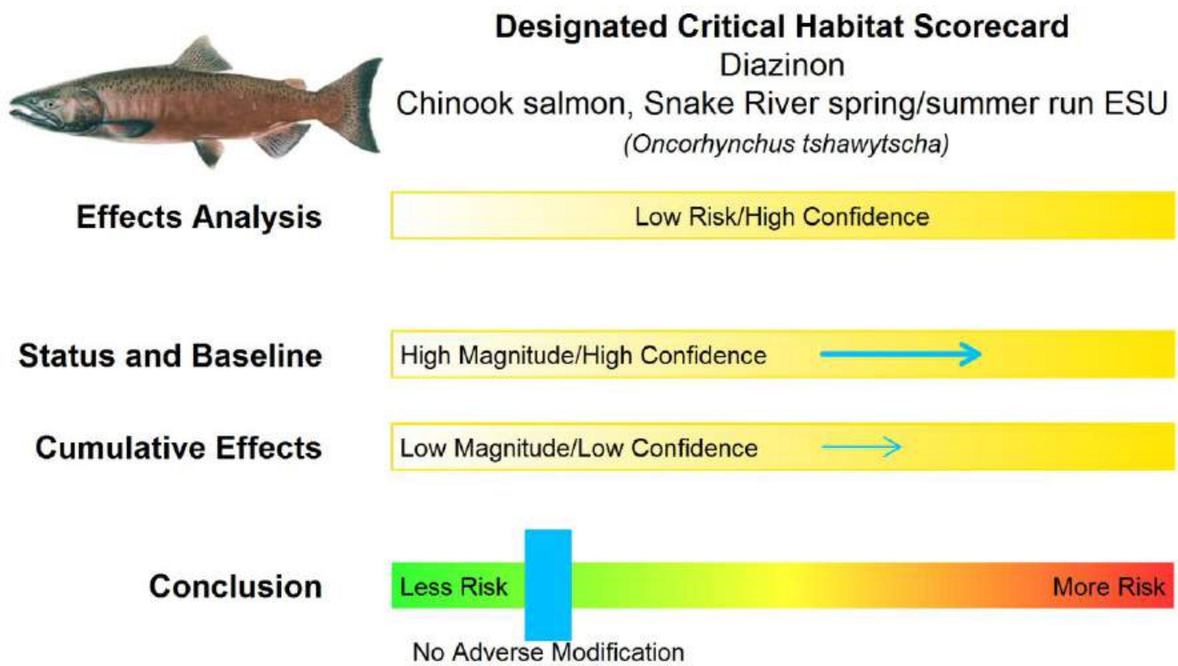

Figure 11. Designated Critical Habitat Scorecard; Chinook salmon, Snake River spring/summer run ESU; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, rearing and migration PBFs are degraded by loss of habitat, altered stream flows, barriers to fish passage, dams, loss of cover, and poor water quality
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire river corridor is considered of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

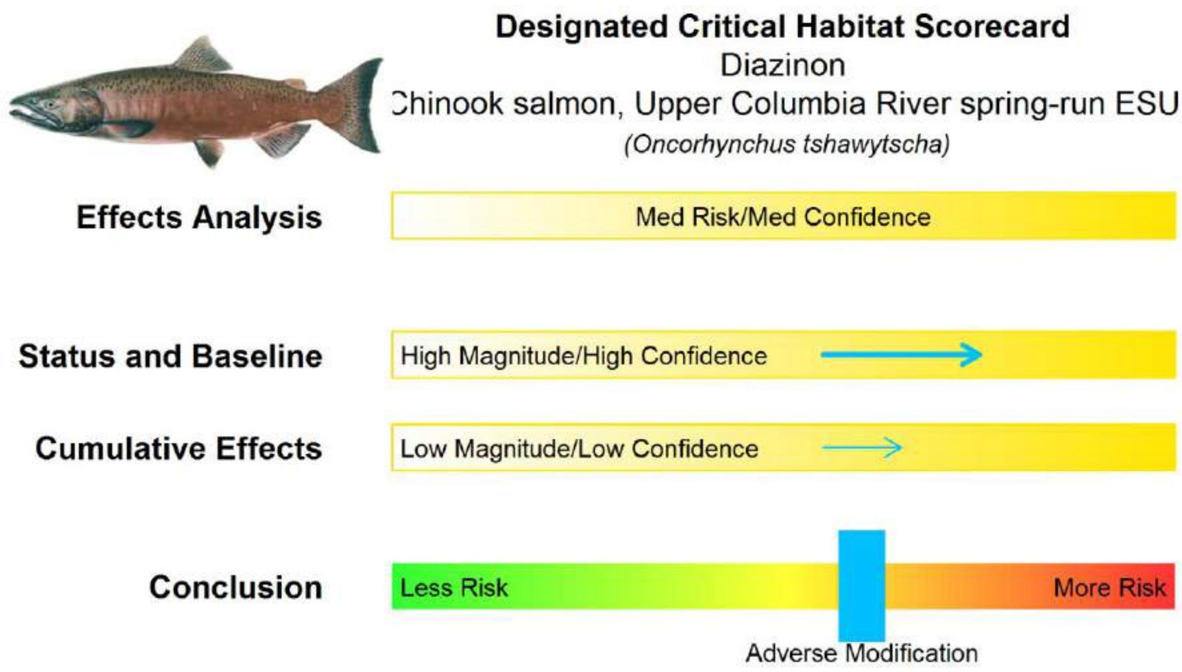

Figure 12. Designated Critical Habitat Scorecard; Chinook salmon, Upper Columbia River spring-run ESU; Diazinon

Effects Analysis: Medium risk/Medium confidence
- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence
- Spawning and rearing PBFs are degraded by urbanization and irrigation water diversions
- Migration PBFs degraded by numerous dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of occupied watersheds, 26 are of high and 5 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence
- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 135,640 acres (over 4% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

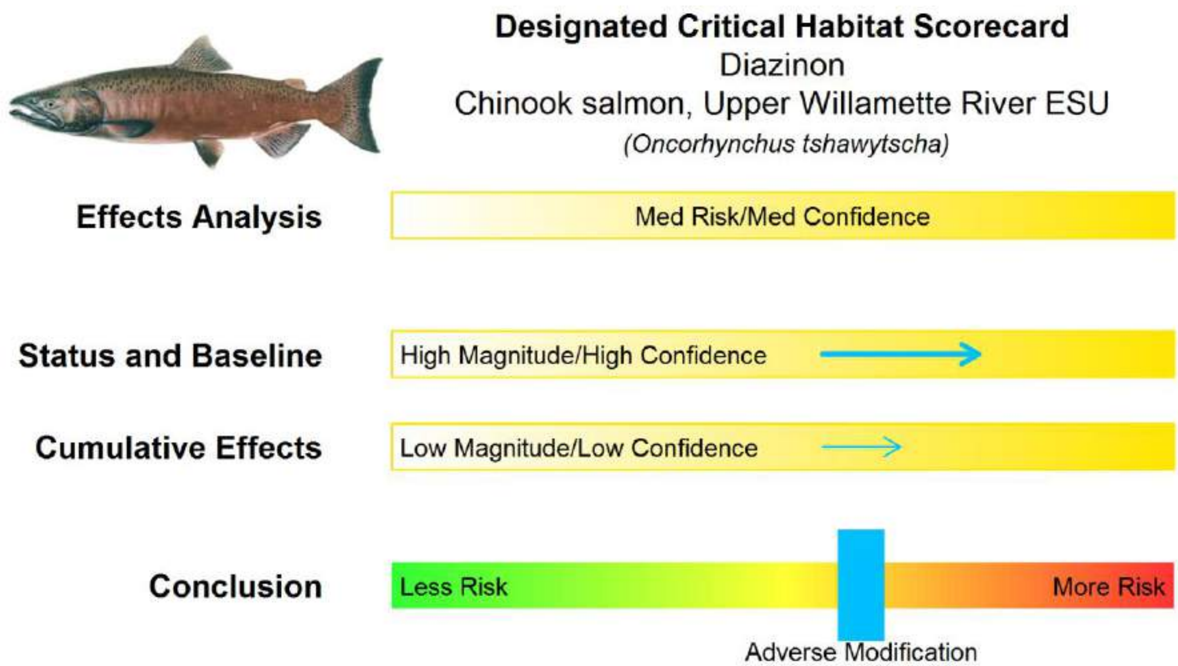

Figure 13. Designated Critical Habitat Scorecard; Chinook salmon, Upper Willamette River ESU; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Migration, rearing, and estuary PBFs are degraded by dams, water management, loss of riparian vegetation, and quality of floodplain habitat
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 59 assessed watersheds, 22 are of high and 18 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 56,510 acres (over 1% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

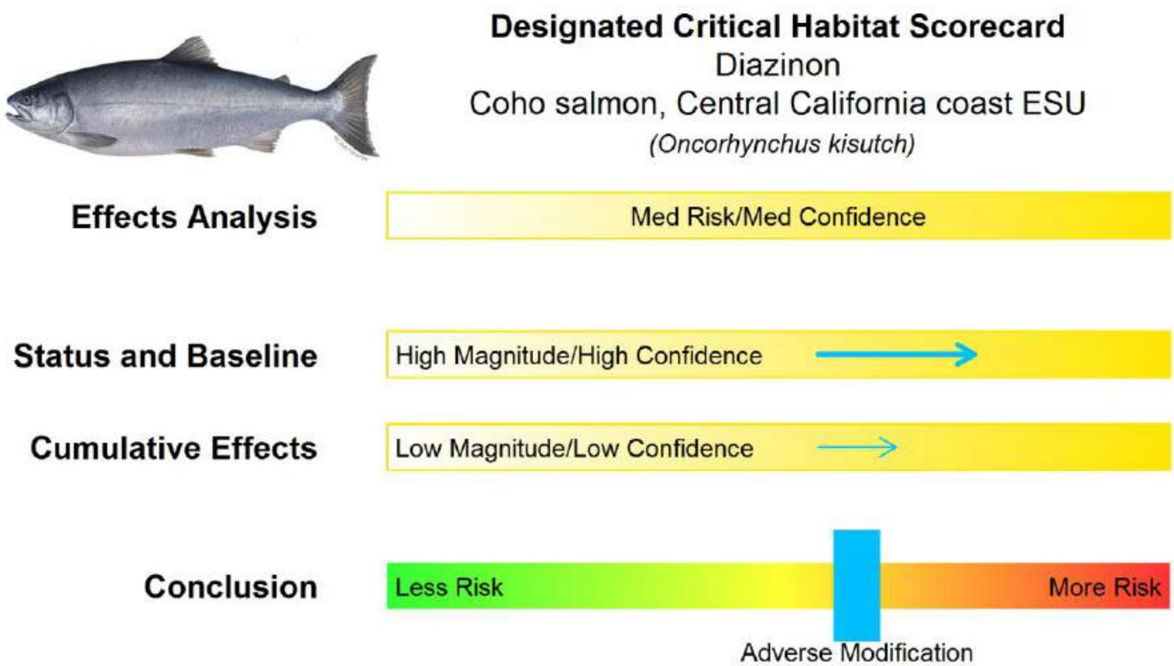

Figure 14. Designated Critical Habitat Scorecard; Coho salmon, Central California coast ESU; Diazinon

<u>Effects Analysis: Medium risk/Medium confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Degradation in quality and quantity of PBFs, especially in southern end of range
- Rearing PBFs degraded by loss of suitable incubation substrate and loss of habitat
- Elevated temperatures anticipated in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats may impact PBFs

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 100,726 acres (more than 3% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

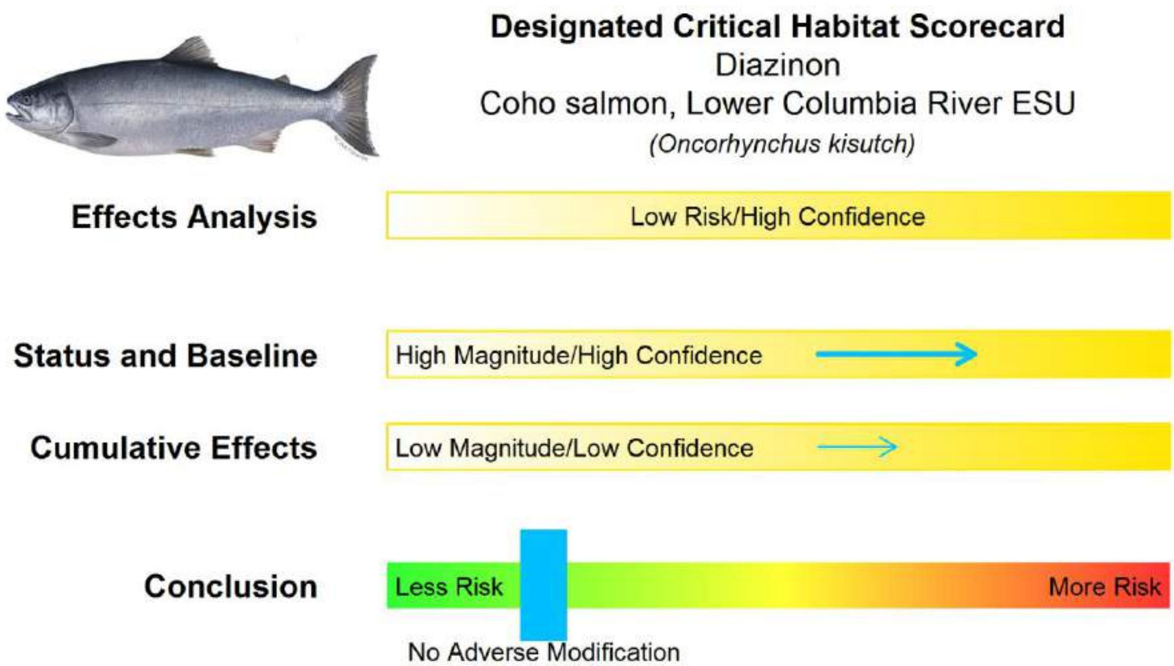

Figure 15. Designated Critical Habitat Scorecard; Coho salmon, Lower Columbia River ESU; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by timber harvest, agriculture, urbanization, loss of floodplain habitat, and reduced natural cover
- Migration PBFs impacted by dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

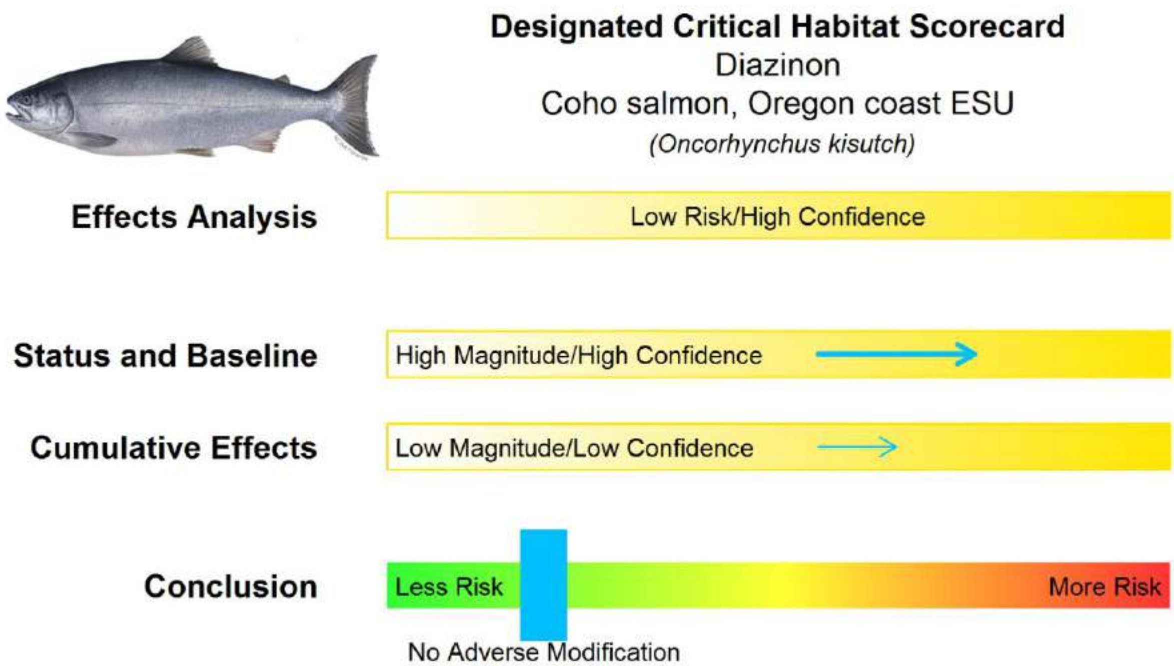

Figure 16. Designated Critical Habitat Scorecard; Coho salmon, Oregon coast ESU; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by elevated water temperature
- All PBFs degraded by reduced water quality from contaminants and excess nutrients
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 80 assessed watersheds, 45 are of high and 27 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

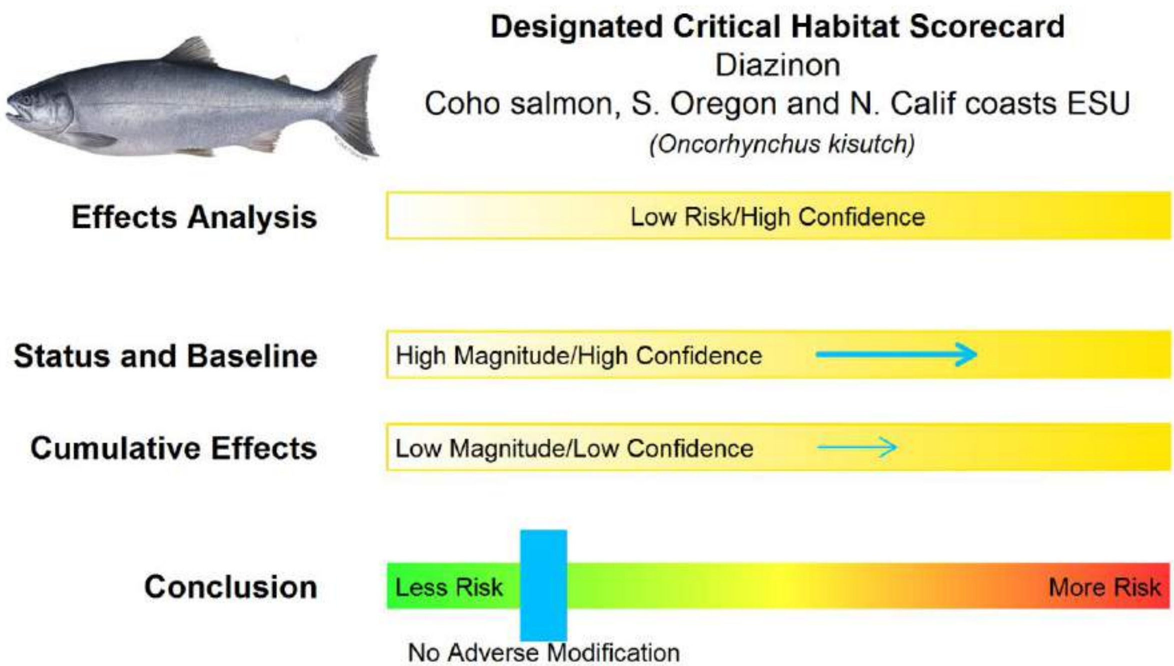

Figure 17. Designated Critical Habitat Scorecard; Coho salmon, S. Oregon and N. Calif coasts ESU; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning PBFs are degraded by logging
- Rearing and migration PBFs degraded by loss of riparian vegetation and loss of floodplain habitat
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

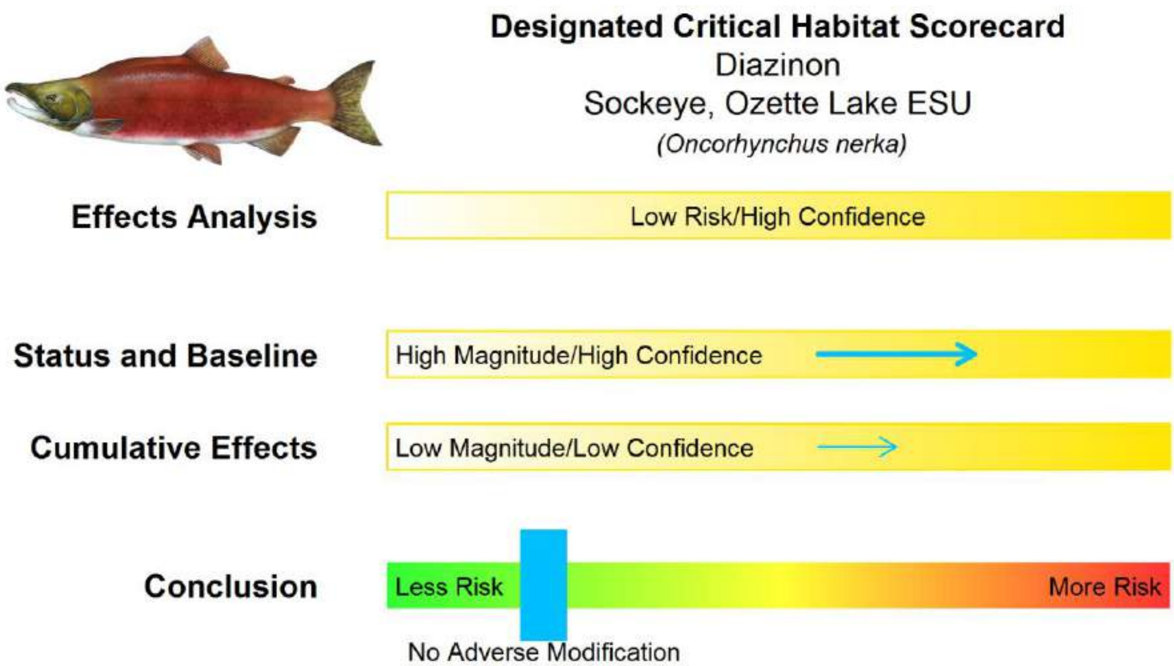

Figure 18. Designated Critical Habitat Scorecard; Sockeye, Ozette Lake ESU; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not ikely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by excessive predation, invasive species, and loss of habitat
- Spawning and migration PBFs are degraded by low water levels, loss of suitable spawning habitat, and low summer water flows
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire watershed is of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to a lack of overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

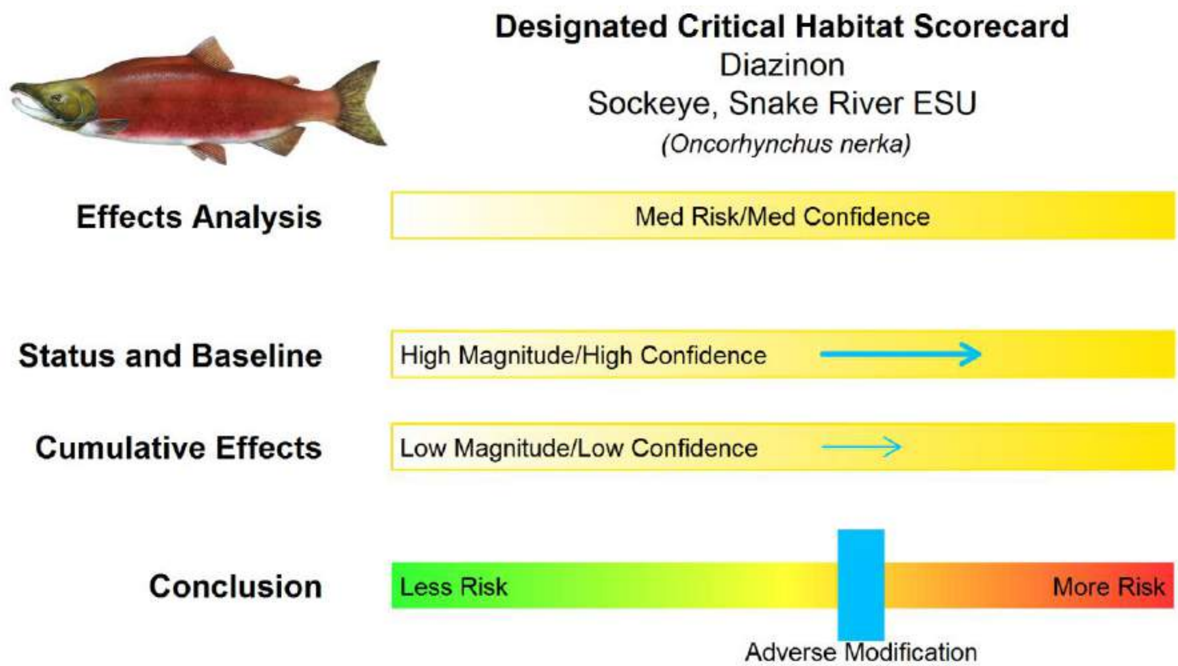

Figure 19. Designated Critical Habitat Scorecard; Sockeye, Snake River ESU; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing and migration PBFs are degraded by impaired water quality from adjacent land uses
- Migration PBFs are degraded by multiple dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- All occupied and used areas of the watershed are of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 58,848 acres (over 1% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

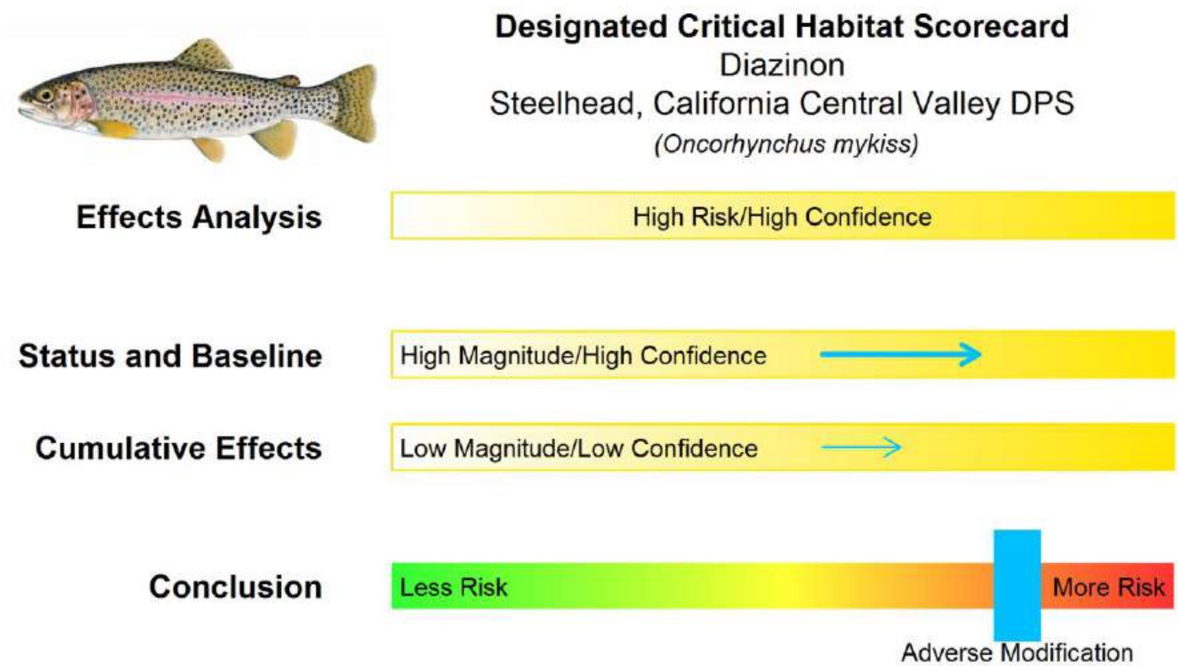

Figure 20. Designated Critical Habitat Scorecard; Steelhead, California Central Valley Distinct Population Segment (DPS); Diazinon

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning Physical and Biological Features (PBFs) are degraded by altered water flows and temperature
- Rearing and migration PBFs are degraded by altered riverine habitat, dense urbanization and agriculture, poor water quality, and water diversions
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 67 occupied watersheds, 37 are of high and 18 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 702,424 acres (over 13% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

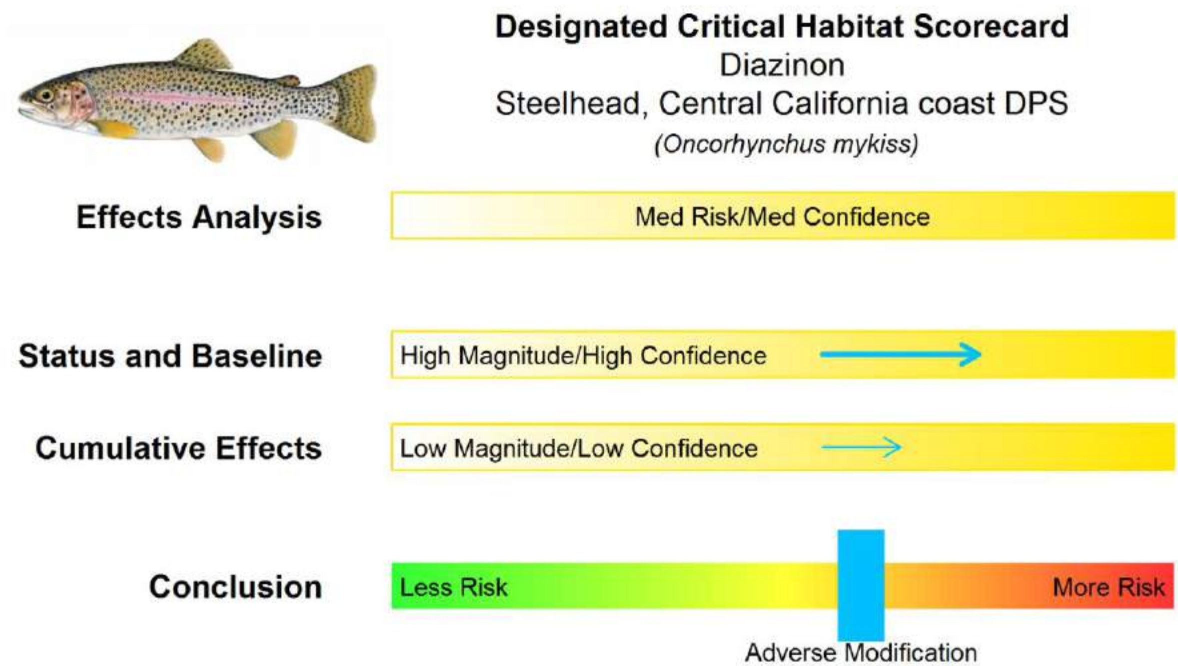

Figure 21. Designated Critical Habitat Scorecard; Steelhead, Central California coast DPS; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by sedimentation and elevated temperature
- All PBFs are degraded by loss of habitat, low summer flows, erosion, and contaminants
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 47 occupied watersheds, 19 are of high and 15 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 95,207 acres (less than 4% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

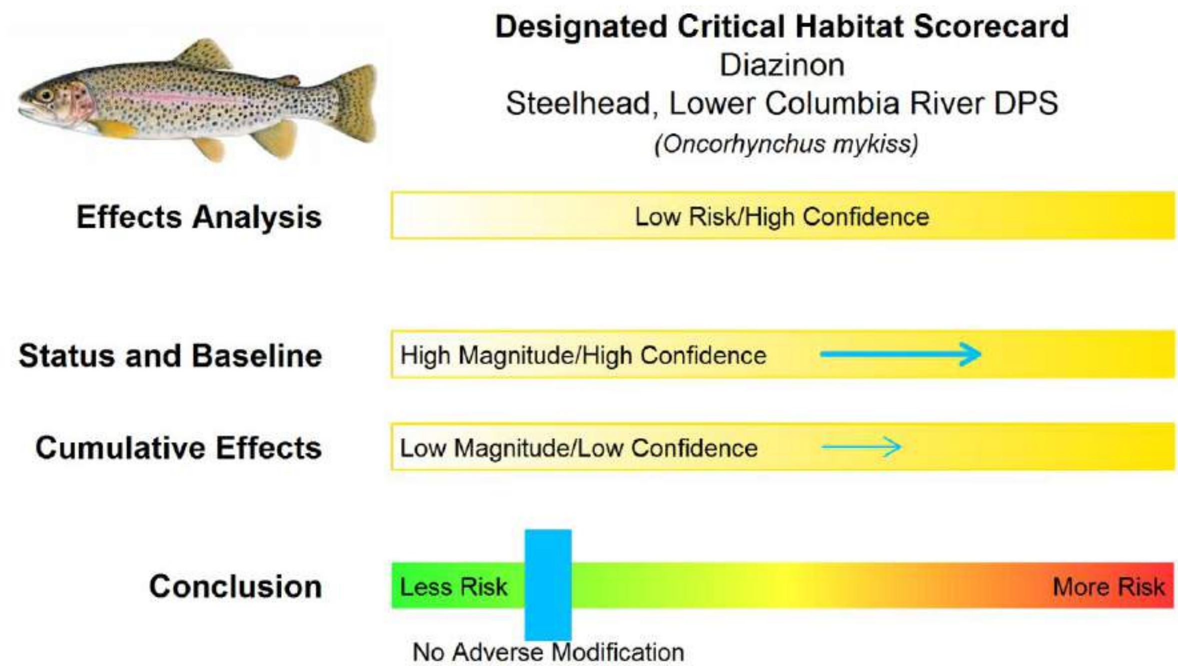

Figure 22. Designated Critical Habitat Scorecard; Steelhead, Lower Columbia River DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by agricultural runoff and lack of available prey
- Spawning, rearing and migration PBFs are degraded by timber harvests, dams, and loss of floodplain habitat
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 41 occupied watersheds, 28 are of high and 11 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

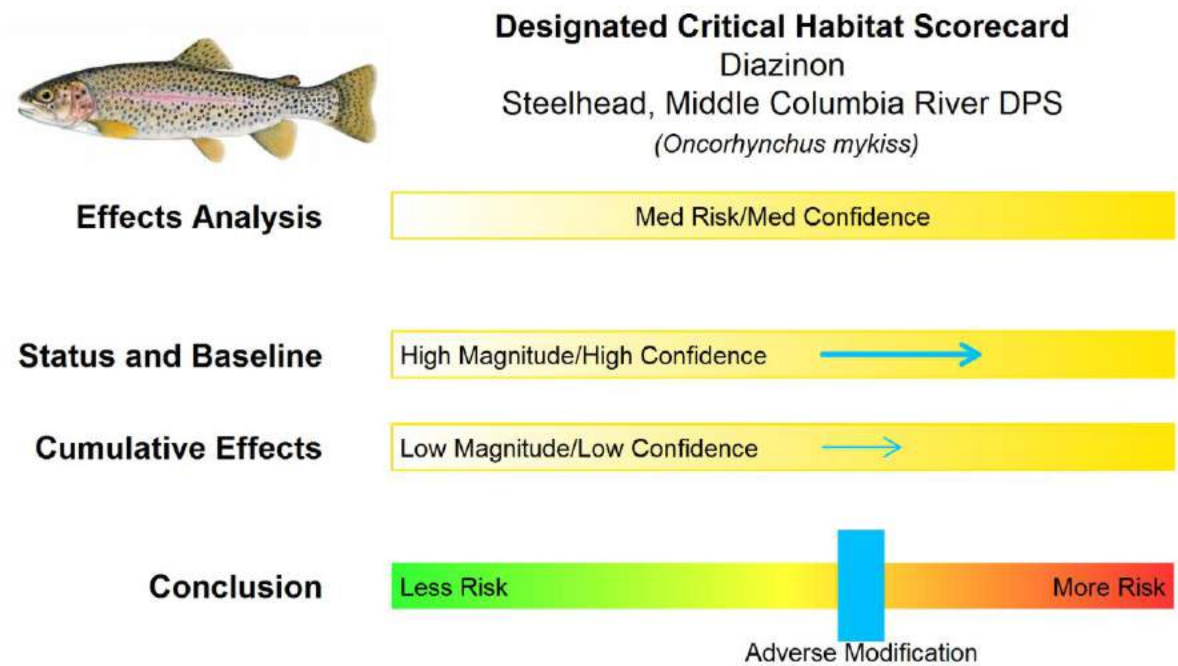

Figure 23. Designated Critical Habitat Scorecard; Steelhead, Middle Columbia River DPS; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by water quality, reduced invertebrate prey, and loss of riparian vegetation
- Migration PBFs are degraded by several dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 106 assessed watersheds, 73 are of high and 24 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 316,948 acres (more than 3% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

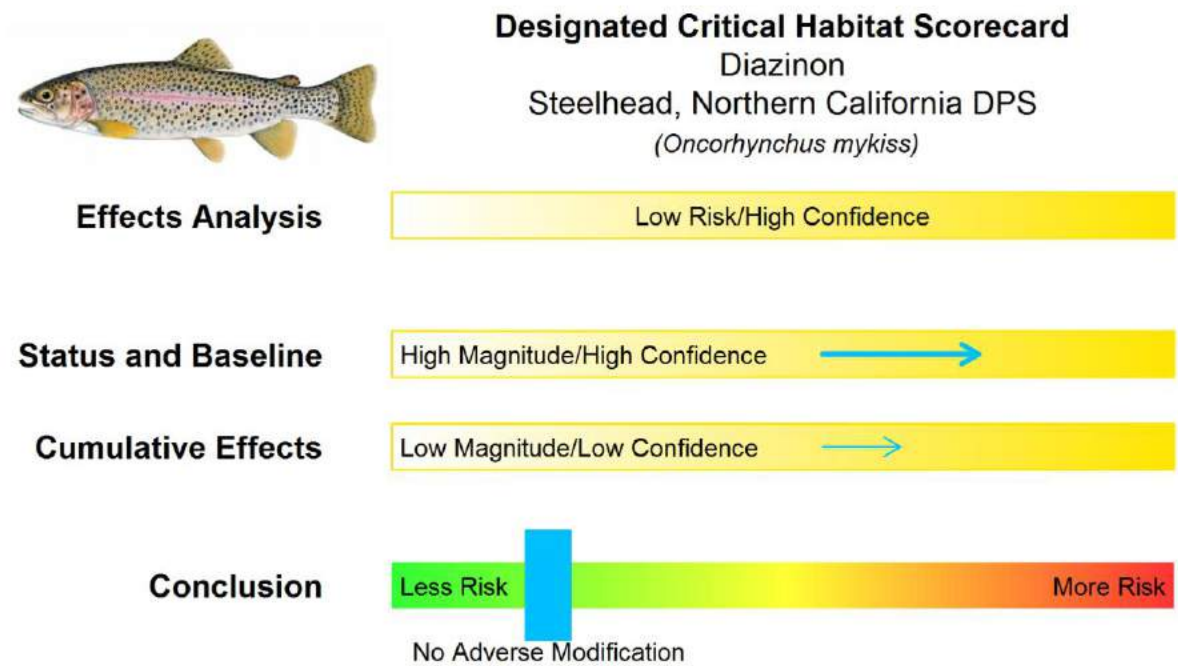

Figure 24. Designated Critical Habitat Scorecard; Steelhead, Northern California DPS; DIazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not ikely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by loss of riparian vegetation and elevated temperature
- Spawning PBFs are degraded by lack of quality substrate and sedimentation
- Migration PBFs are degraded by bridges, culverts, and forest road construction
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 50 assessed watersheds, 27 are of high and 14 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

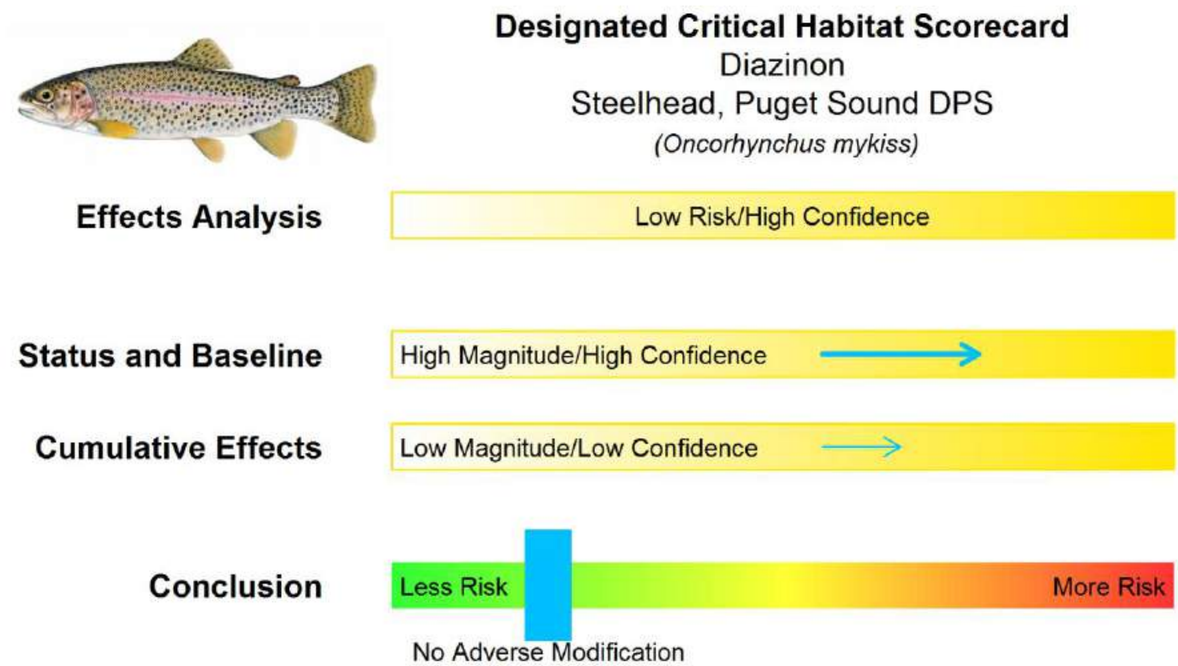

Figure 25. Designated Critical Habitat Scorecard; Steelhead, Puget Sound DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature may increase adverse effects
- We find high confidence of low risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing, migration and spawning PBFs are degraded by forestry, agriculture, urbanization, loss of floodplain habitat, and poor water quality
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Most watersheds are of high or medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a low risk to this species' designated critical habitat due to minimal overlap with diazinon use sites. Reductions in prey and degradation of water quality are not anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

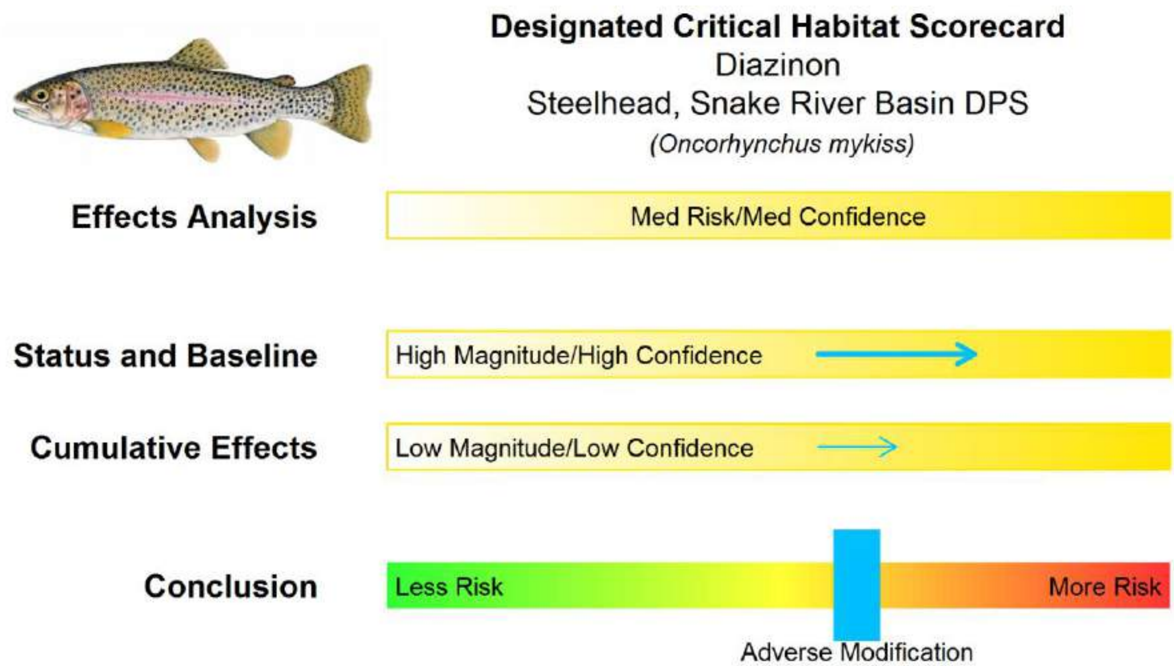

Figure 26. Designated Critical Habitat Scorecard; Steelhead, Snake River Basin DPS; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by agricultural runoff, reduced invertebrate prey, loss of riparian vegetation, and elevated temperature
- Migration PBFs are degraded by several dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of assessed watersheds, 229 are of high and 41 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 188,229 acres (less than 2% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

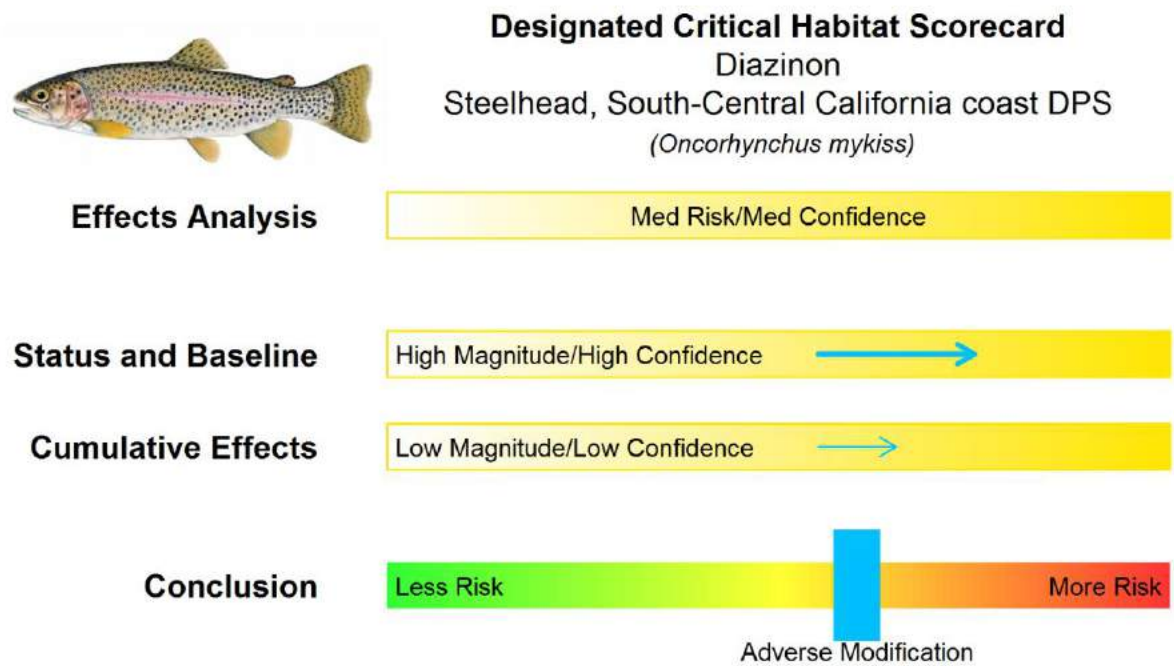

Figure 27. Designated Critical Habitat Scorecard; Steelhead, South-Central California coast DPS; Diazinon

<u>Effects Analysis: Medium risk/Medium confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Rearing and migration PBFs are degraded by elevated temperatures and contaminants from urban and agricultural runoff
- Estuarine PBFs are degraded by altered habitat and contaminated runoff
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 29 occupied watersheds, 12 are of high and 11 are of medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 129,200 acres (4% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

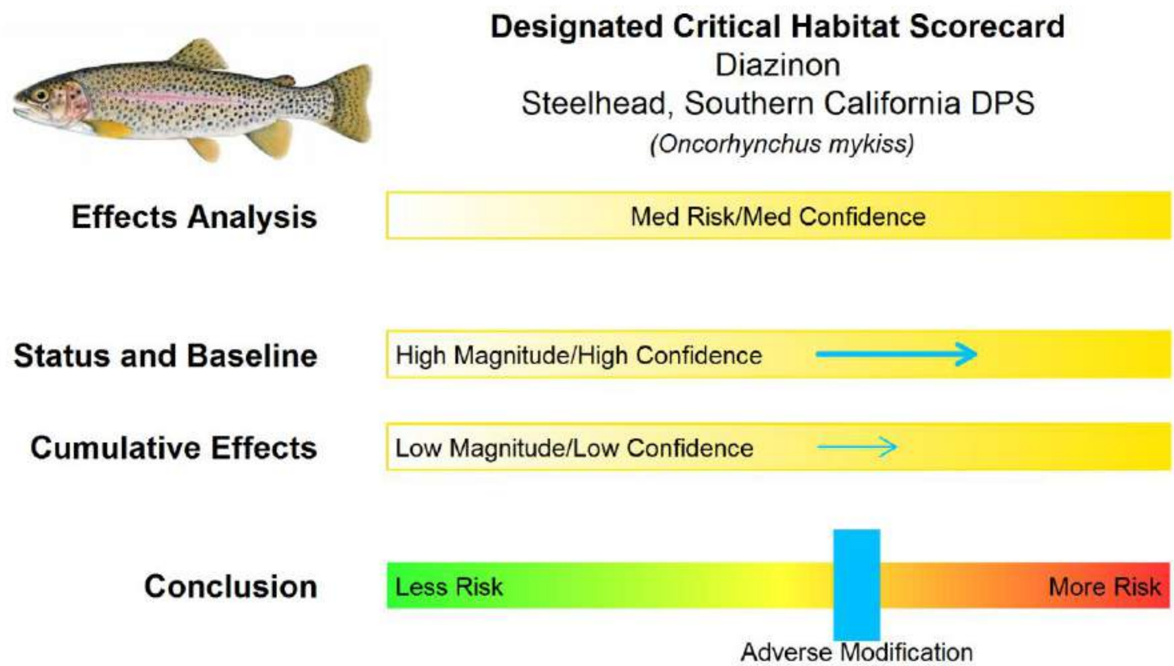

Figure 28. Designated Critical Habitat Scorecard; Steelhead, Southern California DPS; Diazinon

Effects Analysis: Medium risk/Medium confidence
- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence
- All PBFs are degraded by pollutants in urban and agricultural runoff, elevated temperatures, erosion, and low water flows
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 29 freshwater and estuarine watersheds, 21 are of high and 5 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence
- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 25,045 acres (less than 2% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

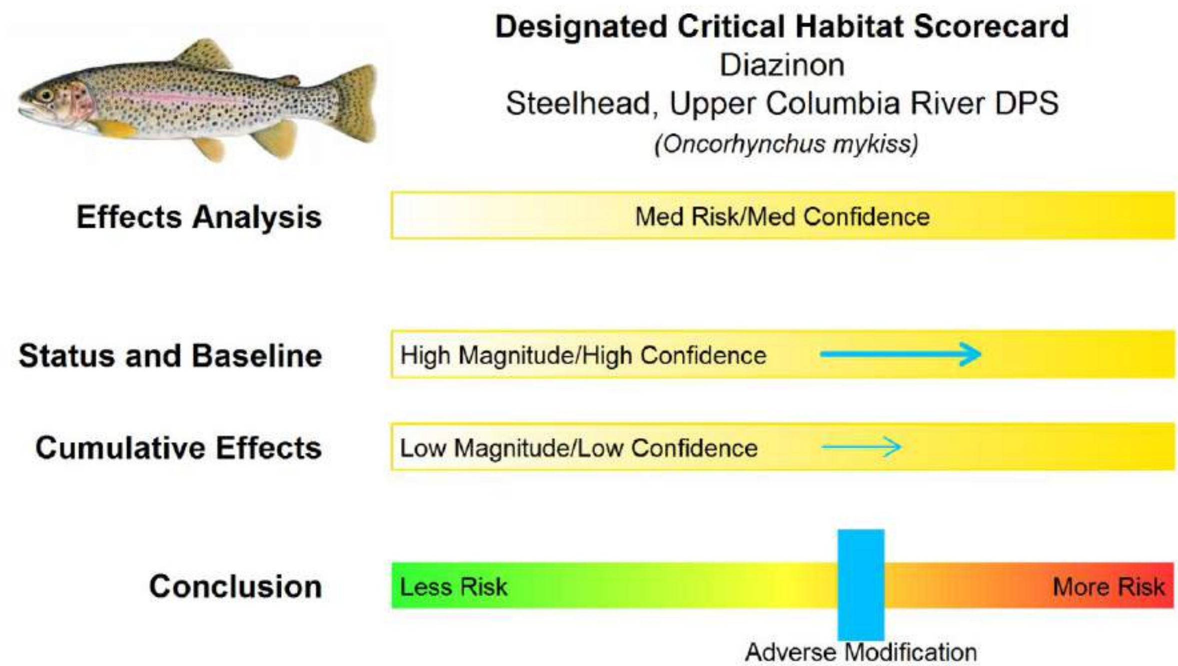

Figure 29. Designated Critical Habitat Scorecard; Steelhead, Upper Columbia River DPS; Diazinon

<u>Effects Analysis: Medium risk/Medium confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Rearing PBFs are degraded by agricultural runoff and lack of available prey
- Migration PBFs are degraded by several dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 41 occupied watersheds, 31 are of high and 7 are of medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 184,048 acres (4% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

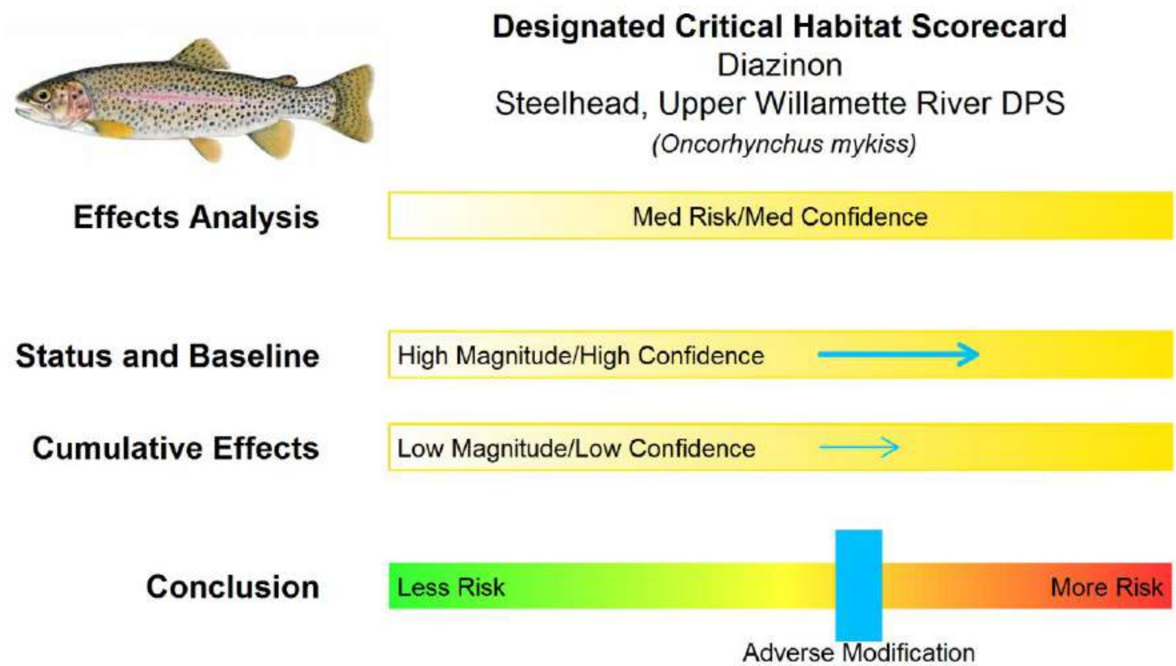

Figure 30. Designated Critical Habitat Scorecard; Steelhead, Upper Willamette River DPS; Diazinon

<u>Effects Analysis: Medium risk/Medium confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find medium confidence of medium risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Rearing PBFs are degraded by agricultural runoff and lack of available prey
- Migration PBFs are degraded by dams and elevated temperatures
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of assessed watersheds, 14 are of high and 6 are of medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find medium confidence of a medium risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 69,784 acres (3% of critical habitat) currently overlap. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

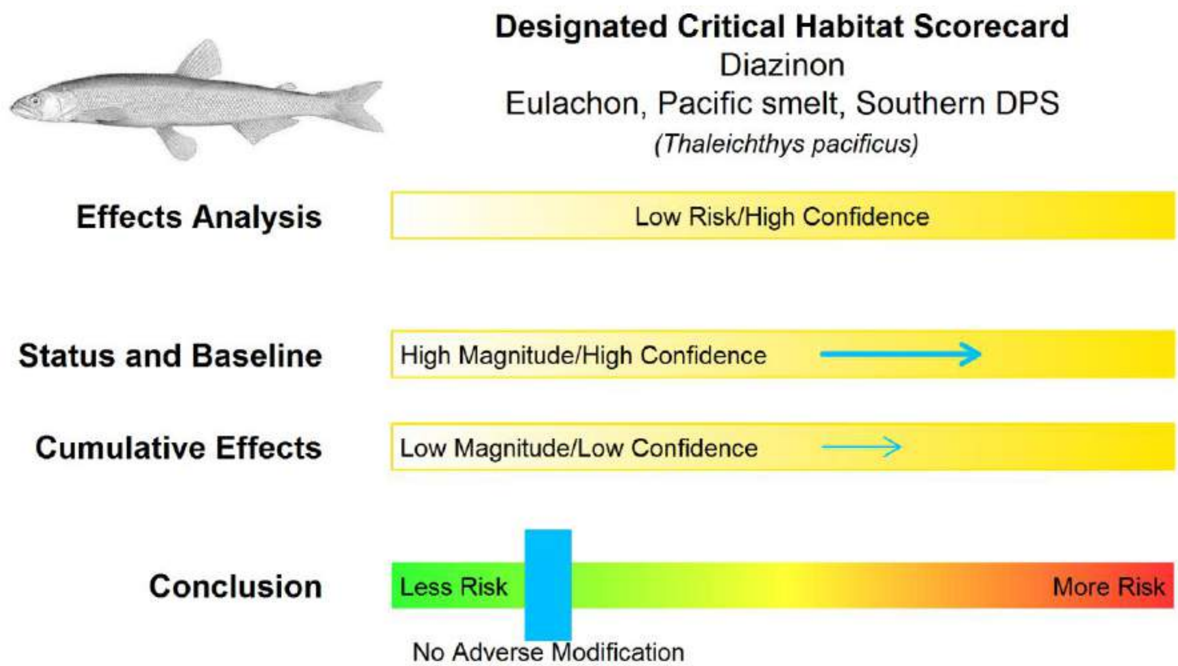

Figure 31. Designated Critical Habitat Scorecard; Eulachon, Pacific smelt, Southern DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, incubation, and rearing PBFs are degraded.
- Dams block flow and access to historical spawning grounds and are cause for degraded spawning substrates below.
- Elevated temperatures prevalent in freshwater habitats.
- Environmental mixtures anticipated in freshwater habitats may affect prey.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten eulachon, particularly in the southern portion of their range where ocean warming trends may be the most pronounced and may alter prey, spawning, and rearing success.
- Anticipated hydrologic changes in freshwater areas may affect PBFs.

Conclusion: We find a low likelihood of exposure and effects to designated critical habitat. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

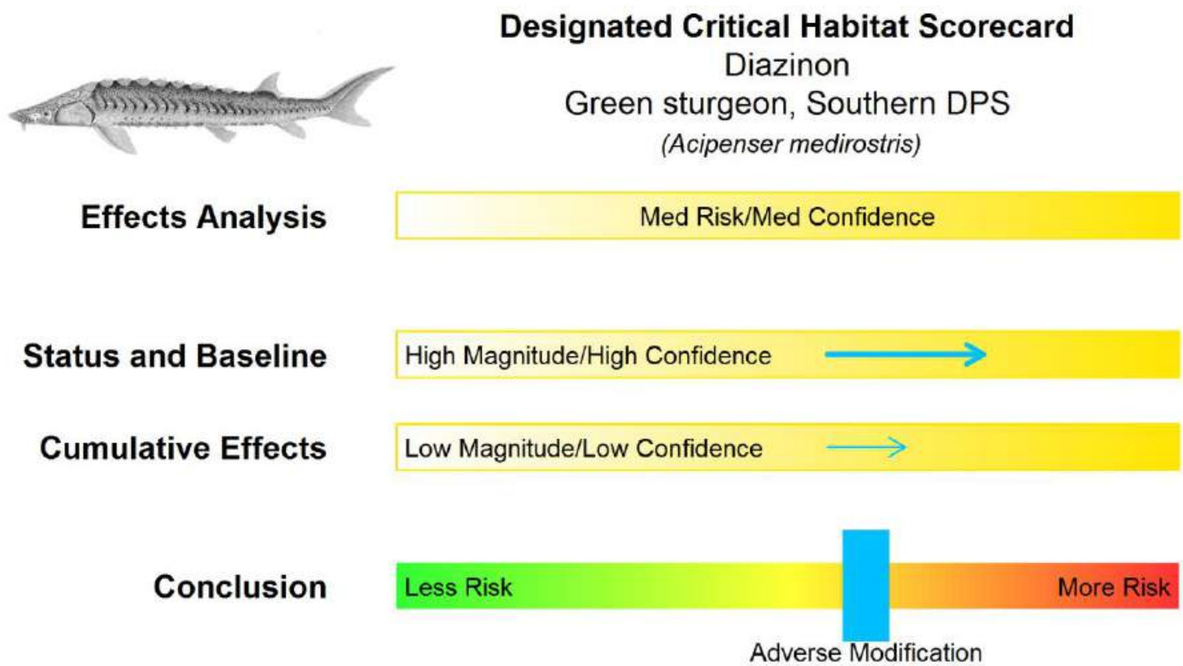

Figure 32. Designated Critical Habitat Scorecard; Green sturgeon, Southern DPS; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find medium confidence of medium risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Insufficient freshwater flow rates in spawning areas.
- Contaminants (e.g., pesticides) prevalent in freshwater habitat.
- Impassable barriers limit spawning to limited sections in Sacramento River.
- Elevated water temperatures persist in freshwater habitat.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Elevated temperatures likely to remain. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a medium likelihood that stressors of the action will negatively affect physical and biological features. Both reductions in prey and degradation of water quality are likely throughout designated critical habitat of this species. Three use site categories, totaling more than 432,870 acres (less than 4 percent of acres) adjacent to critical habitat are currently present. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year duration of the action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

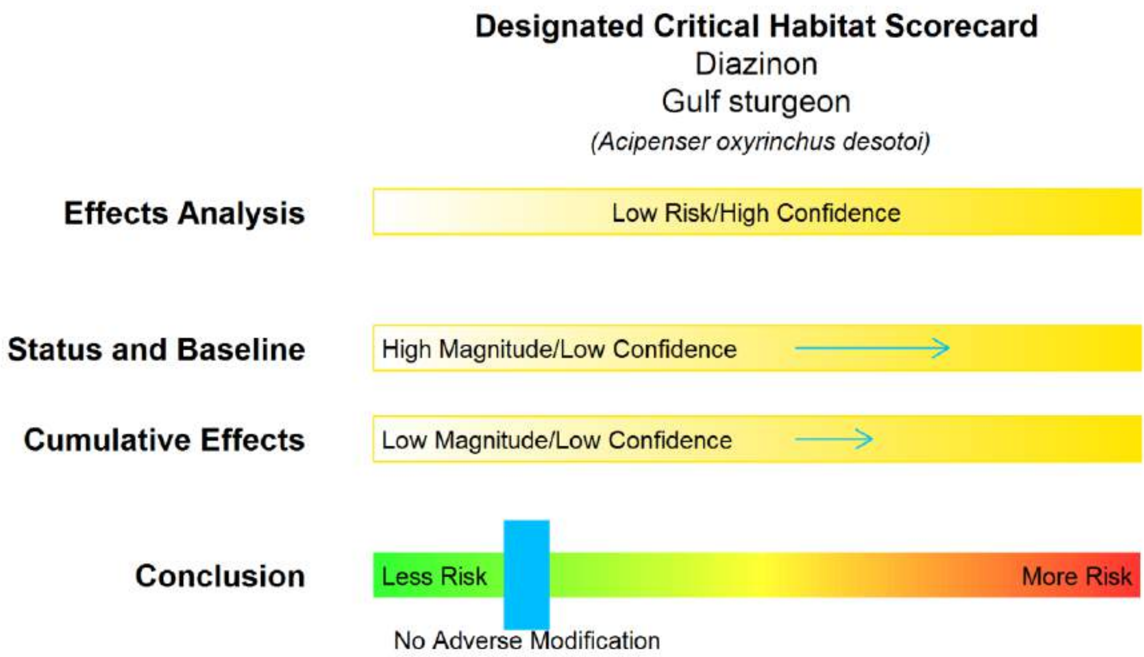

Figure 33. Designated Critical Habitat Scorecard; Gulf sturgeon; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted in their marine habitats.

Status and Baseline: Increased risk; High magnitude/Low confidence

- Construction of water control structures, such as dams and sills exacerbated habitat loss.
- Dredging.
- Groundwater extraction, irrigation, and altered flows.
- Poor water quality.
- Contaminants, primarily from industrial sources.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Global climate change may threaten PBFs.

Conclusion: We have low confidence in EECs predicted for the marine habitats. We find that the overall risk is medium and the confidence associated with that risk is low. We do not anticipate reductions in prey and degradation of water quality will reduce conservation values throughout the marine portion of this species designated critical habitat over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

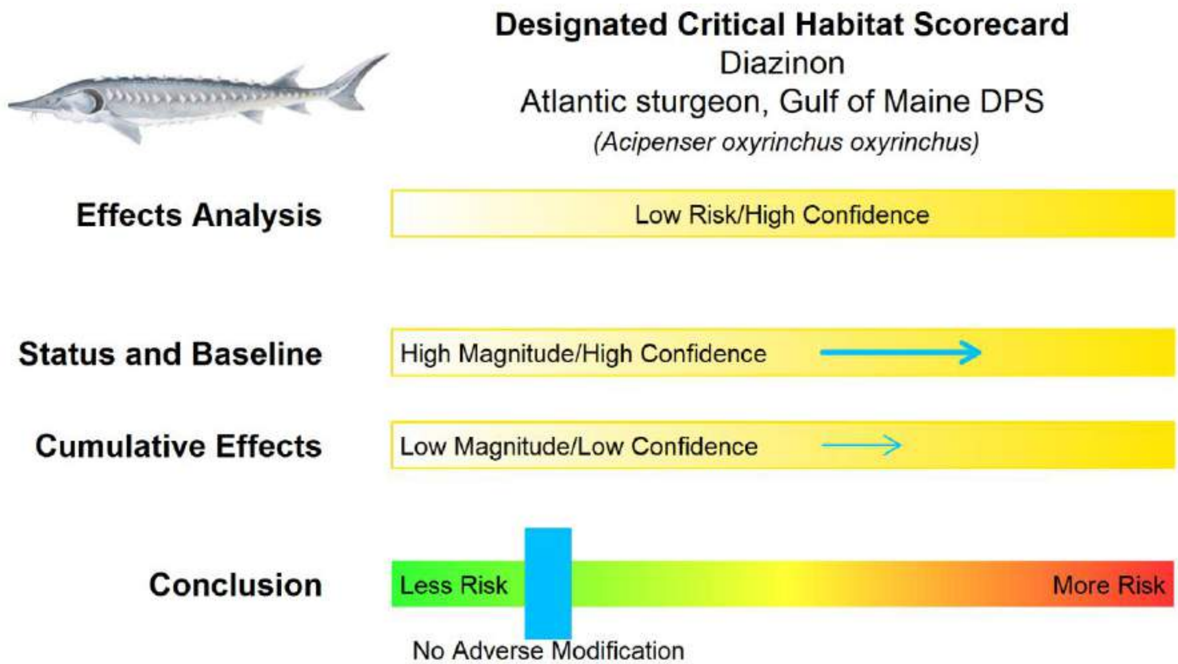

Figure 34. Designated Critical Habitat Scorecard; Atlantic sturgeon, Gulf of Maine DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a low likelihood of exposure and effects to designated critical habitat. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

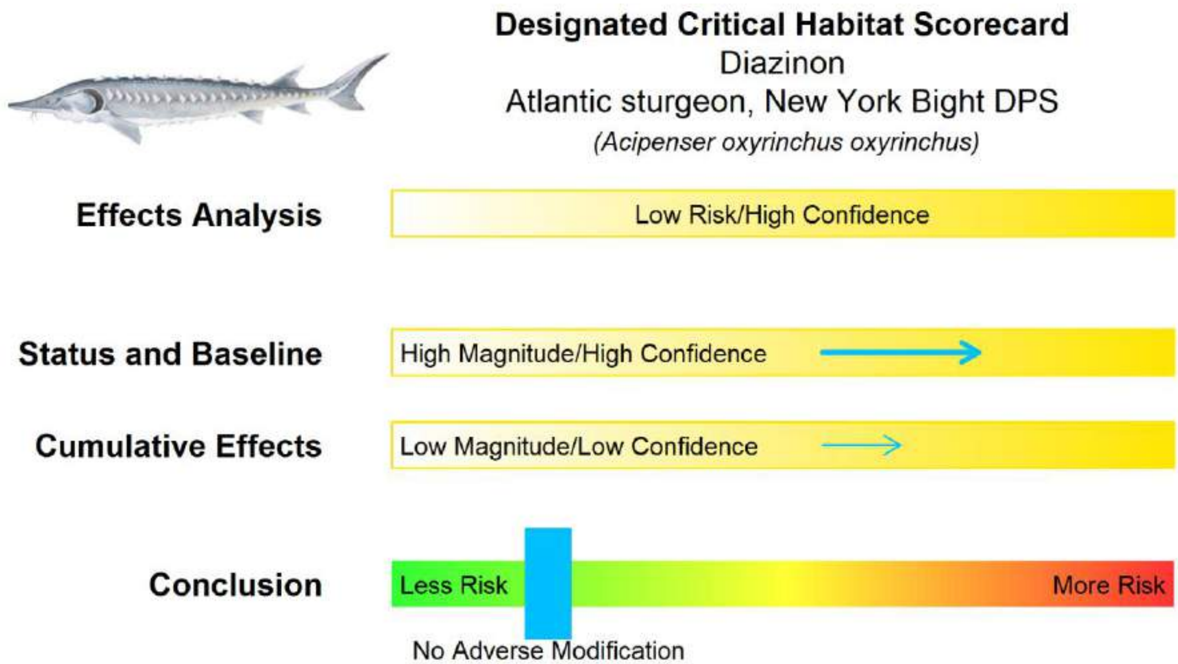

Figure 35. Designated Critical Habitat Scorecard; Atlantic sturgeon, New York Bight DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a low likelihood of exposure and effects to designated critical habitat. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

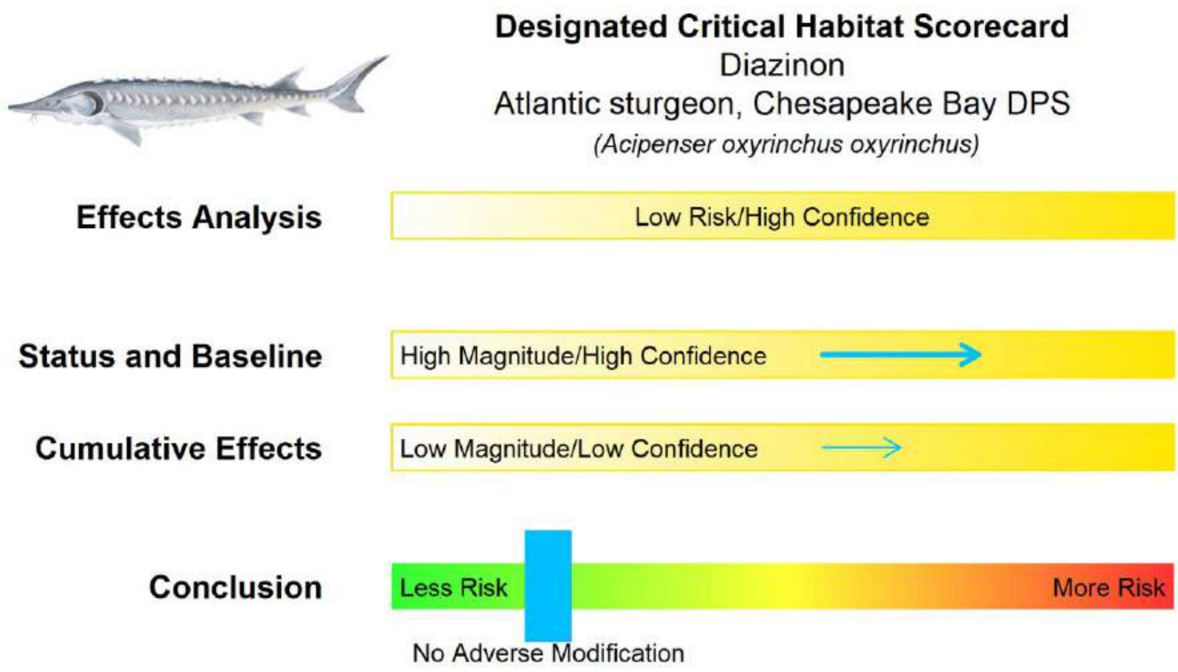

Figure 36. Designated Critical Habitat Scorecard; Atlantic sturgeon, Chesapeake Bay DPS; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

<u>Conclusion:</u> We find a low likelihood of exposure and effects to designated critical habitat. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

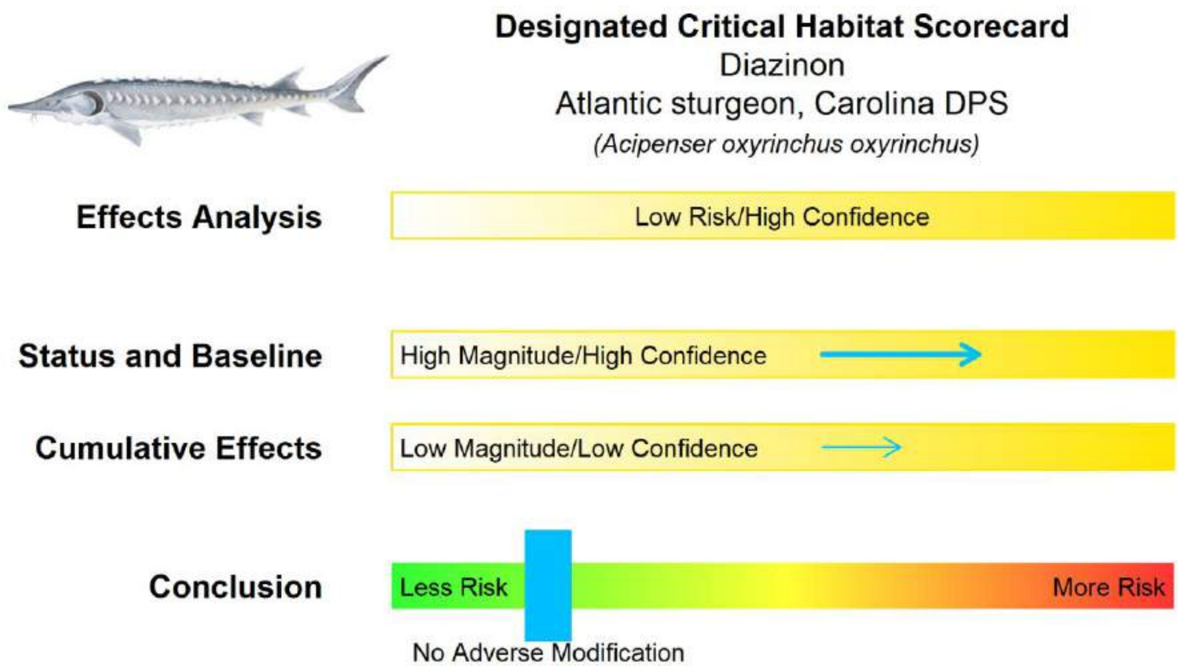

Figure 37. Designated Critical Habitat Scorecard; Atlantic sturgeon, Carolina DPS; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

<u>Conclusion:</u> We find a low likelihood of exposure and effects to designated critical habitat. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

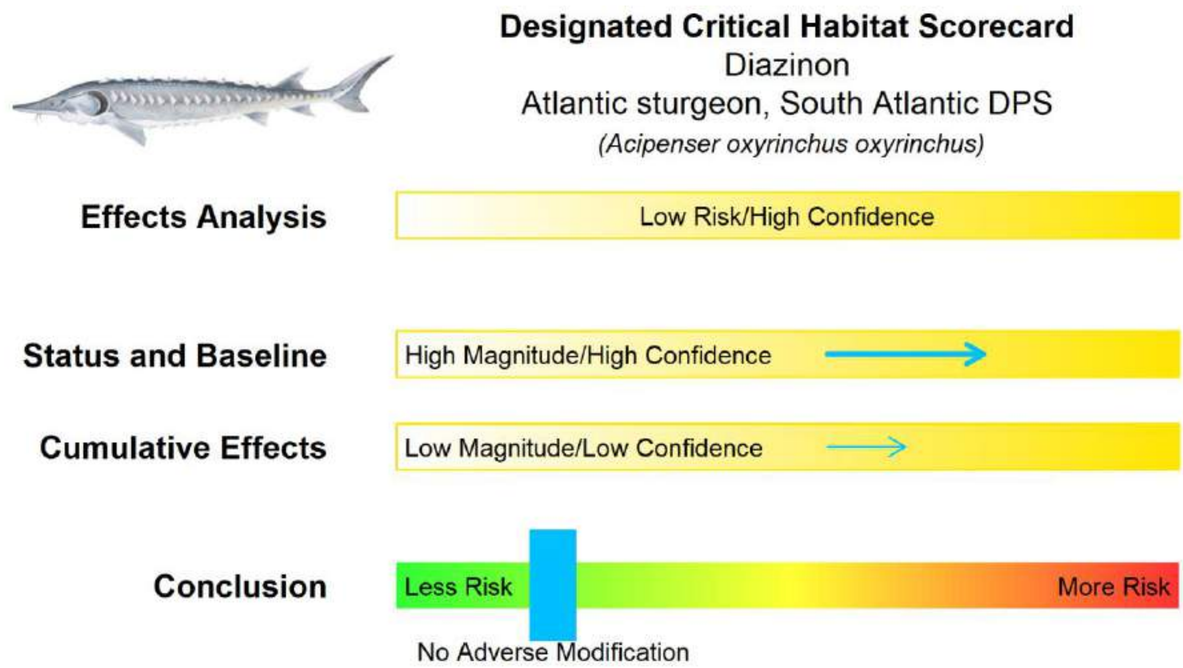

Figure 38. Designated Critical Habitat Scorecard; Atlantic sturgeon, South Atlantic DPS; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a low likelihood of exposure and effects to designated critical habitat. The magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease. Overall the risk is low and the confidence associated with that risk is high due to the exposures predicted in freshwater habitats over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

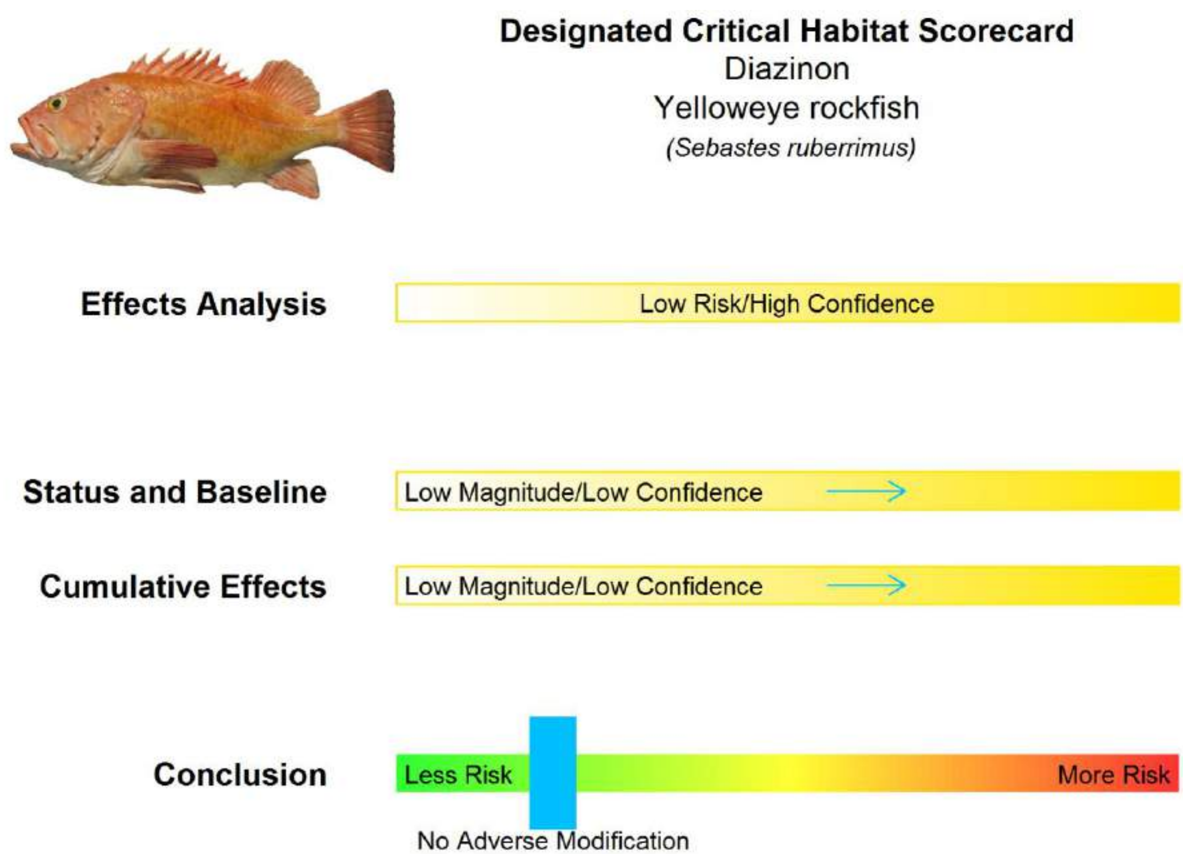

Figure 39. Designated Critical Habitat Scorecard; Yelloweye rockfish; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted in their marine habitats.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Adverse environmental factors have led to prey reductions and recruitment failures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.

Conclusion: We find that the overall risk is low and the confidence associated with that risk is high. We do not anticipate reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

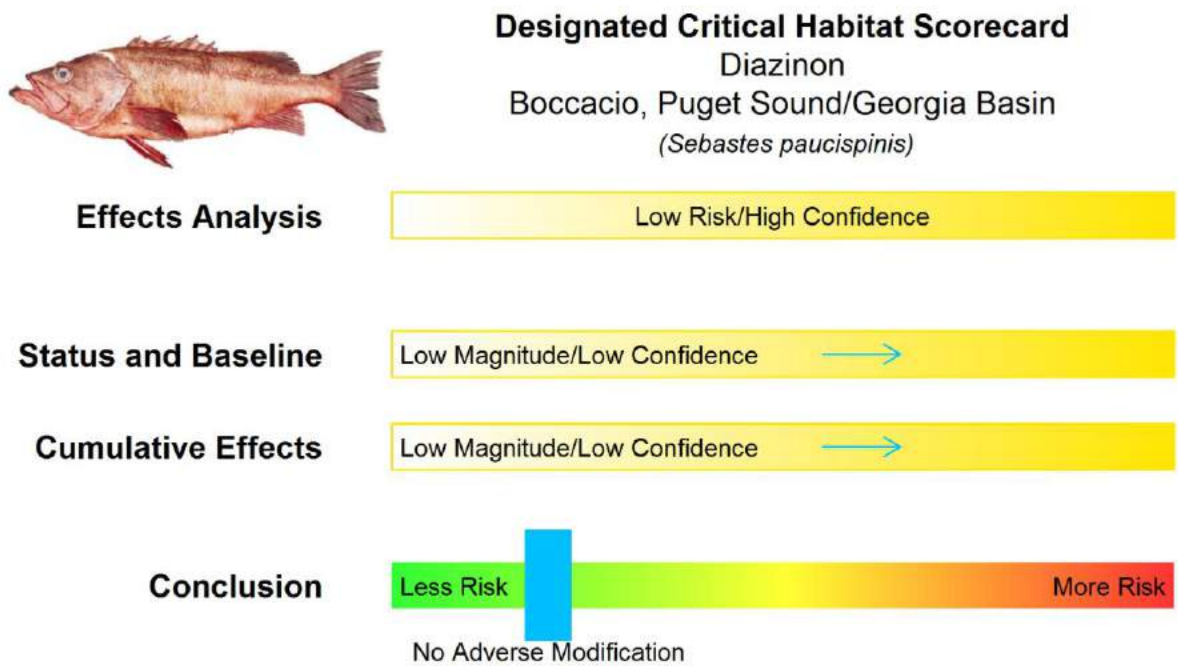

Figure 40. Designated Critical Habitat Scorecard; Boccacio, Puget Sound/Georgia Basin; Diazinon

Effects Analysis: Low risk/High confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted in their marine habitats.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Adverse environmental factors have led to prey reductions and recruitment failures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.

Conclusion: We find that the overall risk is low and the confidence associated with that risk is high. We do not anticipate reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

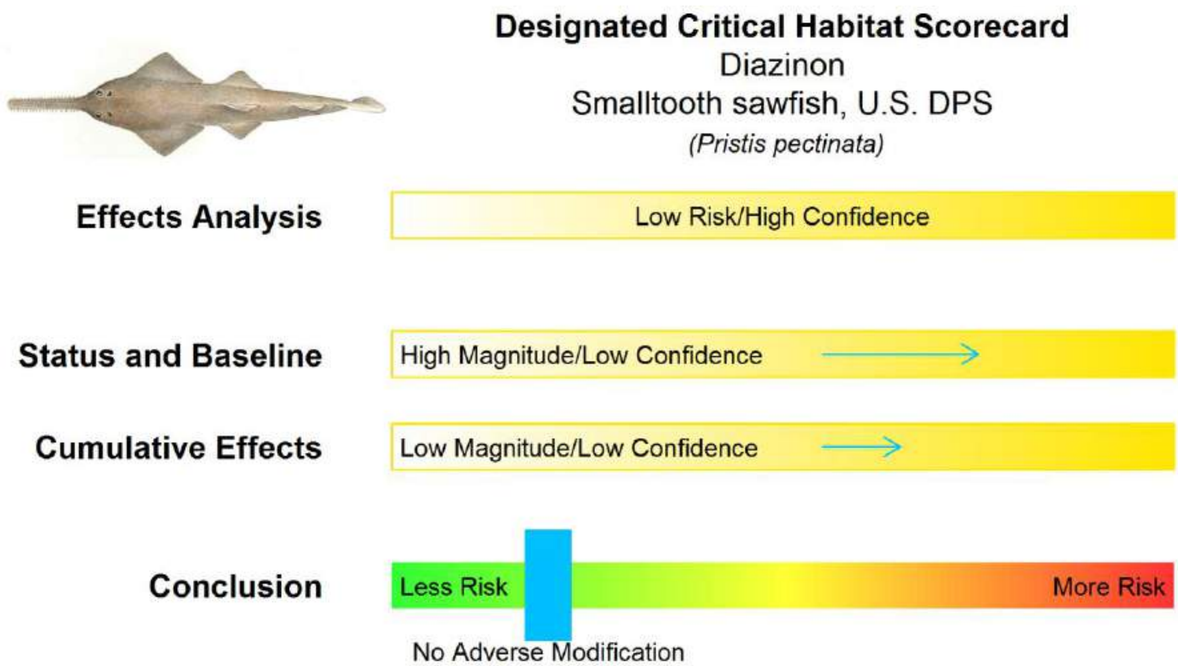

Figure 41. Designated Critical Habitat Scorecard; Smalltooth sawfish, U.S. DPS; Diazinon

<u>Effects Analysis: Low risk/High confidence</u>

- Reductions in prey species and degradation of water quality are not likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to expected exposures predicted in habitats.

<u>Status and Baseline: Increased risk; High magnitude/Low confidence</u>

- Loss and degradation of female pupping sites and juvenile rearing habitats.
- Point and non-point contaminants.
- Marine Debris.

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future losses in vegetated shallow water habitats from developmental pressures, changes in ocean conditions, and hydrology may further threaten PBFs.

<u>Conclusion:</u> We do not anticipate that the stressors of the action will negatively affect physical or biological features (PBFs). Neither reductions in prey, nor degradation of water quality are likely throughout designated critical habitat of Smalltooth Sawfish. The low magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses, the overall conservation value of designated critical habitat is not anticipated to decrease over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

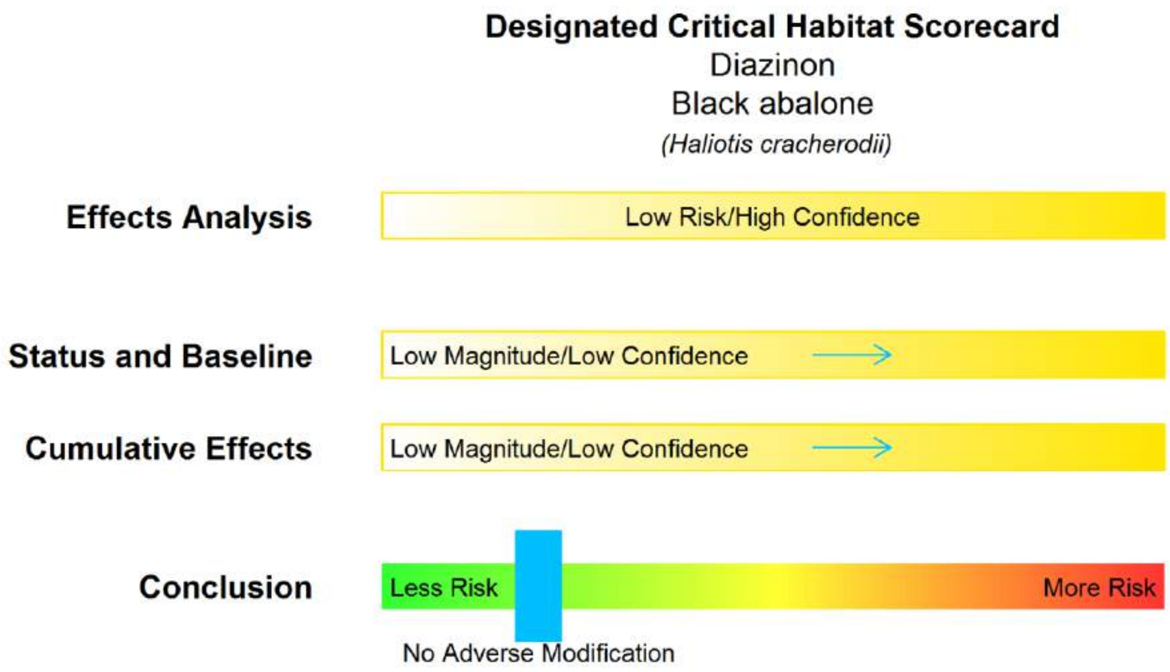

Figure 42. Designated Critical Habitat Scorecard; Black abalone; Diazinon

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in prey species and degradation of water quality in marine nearshore and inter-tidal habitats to reduce the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Habitat destruction.
- Disease.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Developmental pressures could reduce available habitat and create competition for space with other marine invertebrates.
- Changes in ocean conditions (ocean acidification) may threaten PBFs.

Conclusion: We do not anticipate that the stressors of the action will negatively affect physical or biological features. Neither reductions in prey, nor degradation of water quality are likely throughout designated critical habitat of Black Abalone. The low magnitude of toxic effects may result in some adverse effects, however due to the minimal extent of diazinon-containing uses the overall conservation value of designated critical habitat is not anticipated to decrease during the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

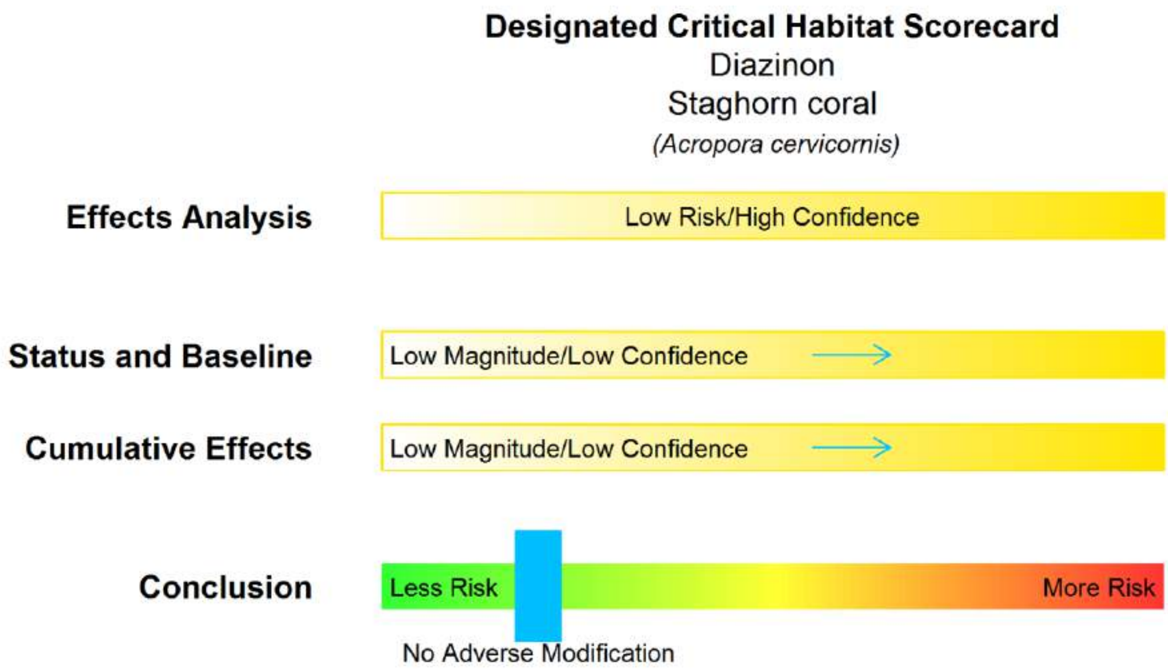

Figure 43. Designated Critical Habitat Scorecard; Staghorn coral; Diazinon

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in PBFs or reductions in the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted and PBFs identified.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease (white band).
- Habitat destruction.
- Bleaching (temperature variations).
- Sedimentation.
- Algal overgrowth (nutrification).

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions (e.g. increased water temperature and acidification) may threaten PBFs.

Conclusion: There are no physical and biological features identified in Staghorn Coral designated critical habitat that could be affected by the proposed action. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

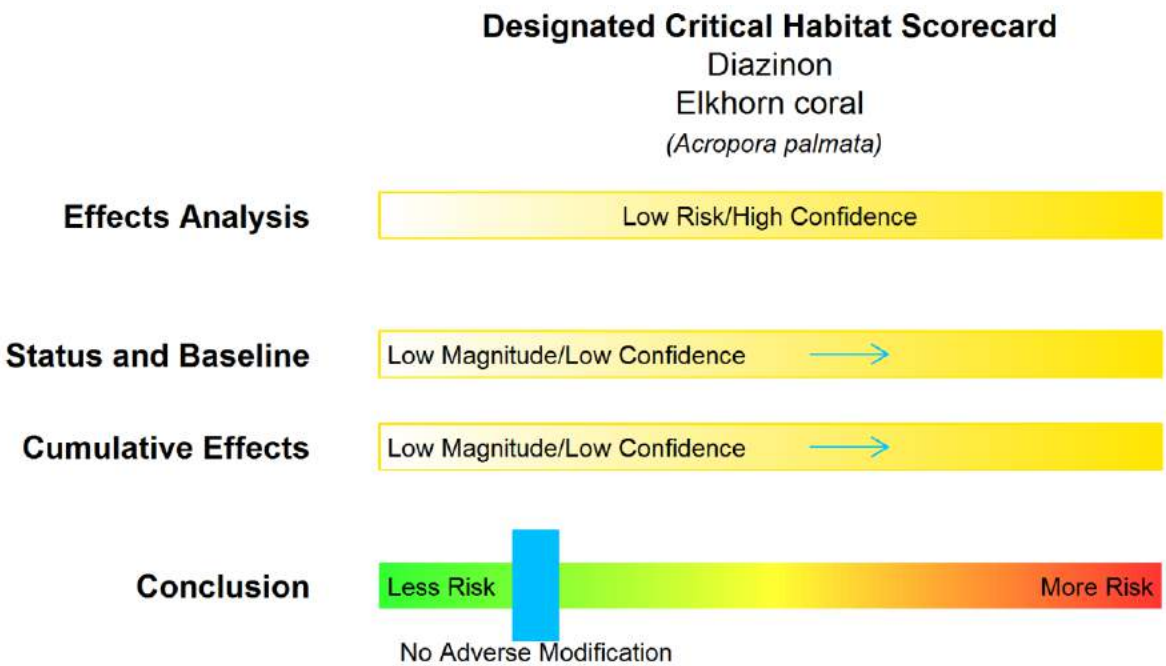

Figure 44. Designated Critical Habitat Scorecard; Elkhorn coral; Diazinon

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in PBFs or reductions in the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted and PBFs identified.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease (white band).
- Habitat destruction.
- Bleaching (temperature variations).
- Sedimentation.
- Algal overgrowth (nutrification).

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions (e.g. increased water temperature and acidification) may threaten PBFs.

Conclusion: There are no physical and biological features identified in Elkhorn Coral designated critical habitat that could be affected by the proposed action. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

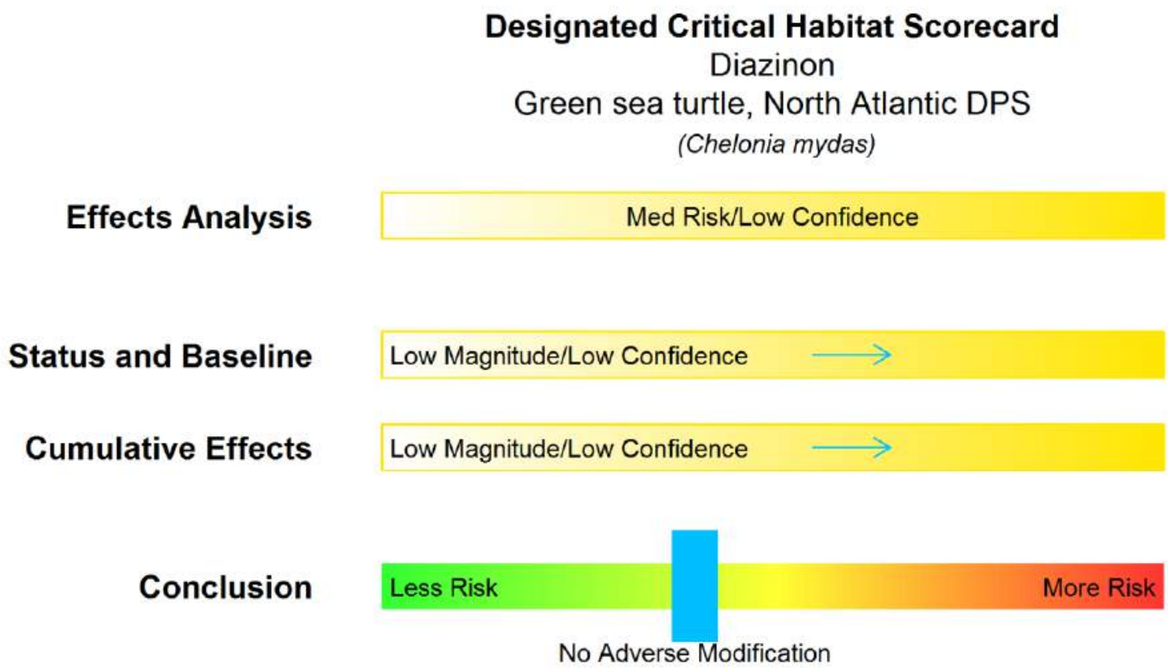

Figure 45. Designated Critical Habitat Scorecard; Green sea turtle, North Atlantic DPS; Diazinon

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in water quality in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease.
- Point and non-point pollution.
- Marine debris continues to build in critical habitat.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical or biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

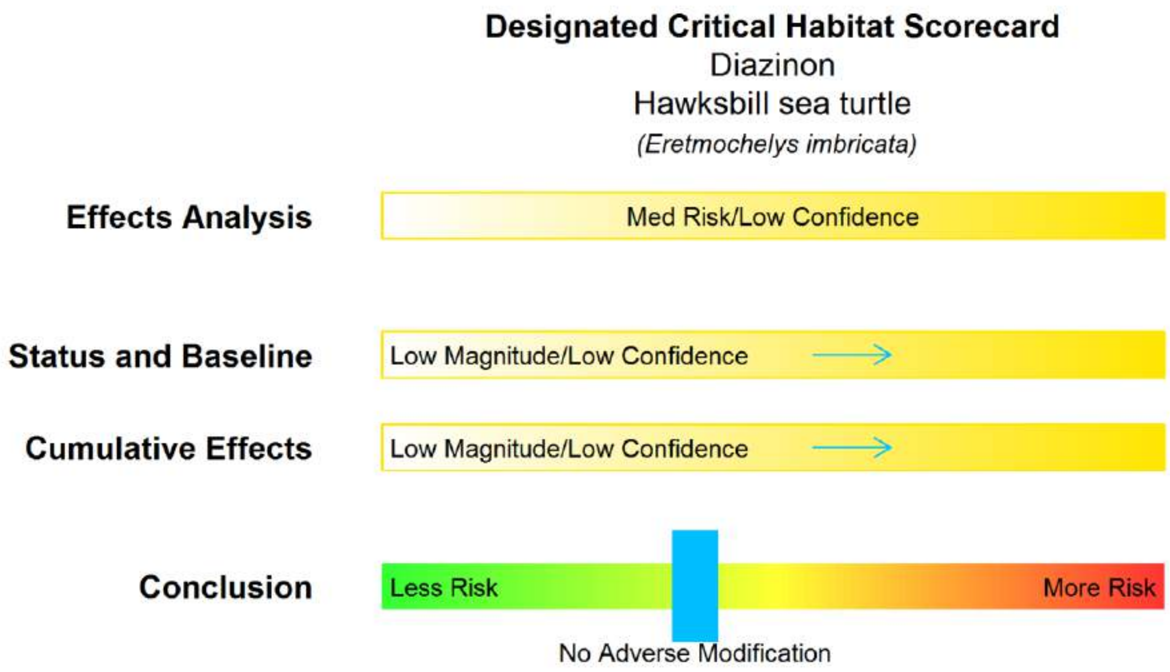

Figure 46. Designated Critical Habitat Scorecard; Hawksbill sea turtle; Diazinon

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in water quality in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease.
- Point and non-point pollution.
- Marine debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical and biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

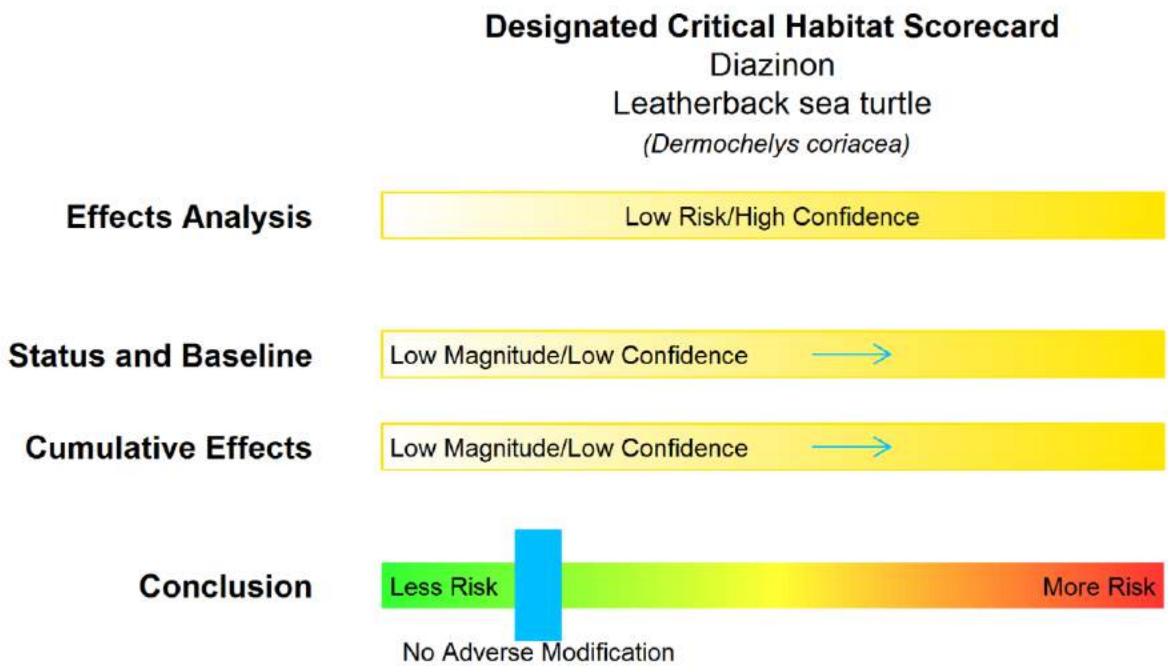

Figure 47. Designated Critical Habitat Scorecard; Leatherback sea turtle; Diazinon

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease.
- Point and non-point pollution.
- Marine debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action are not expected to negatively affect physical or biological features within nearshore designated critical habitat of Leatherback Sea Turtle. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

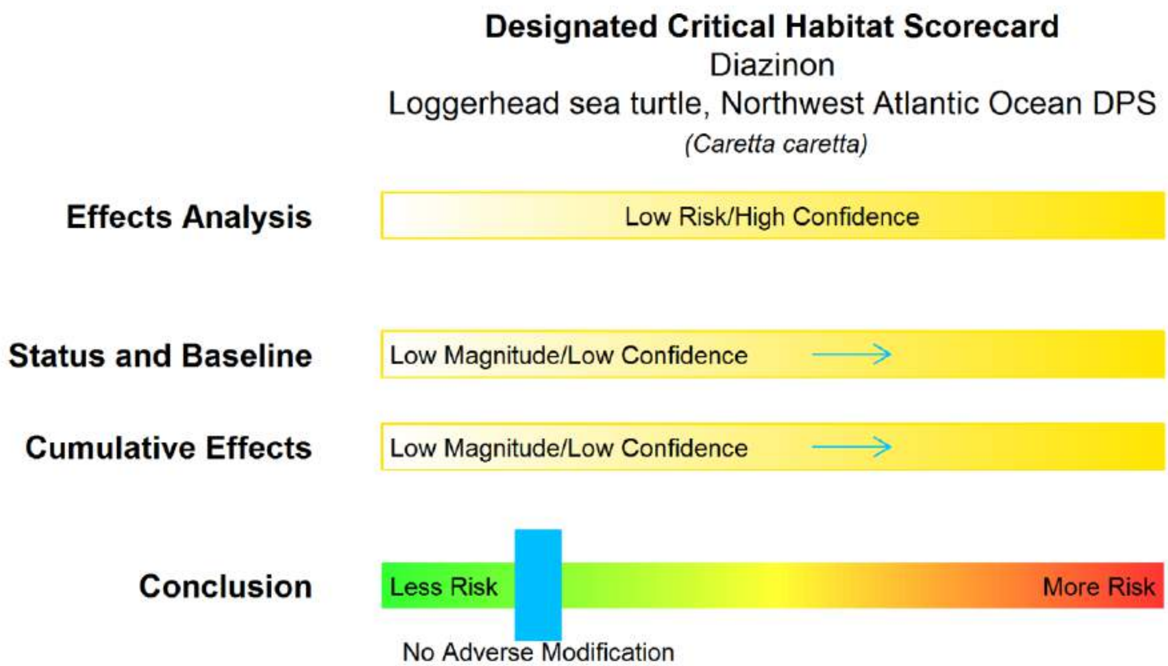

Figure 48. Designated Critical Habitat Scorecard; Loggerhead sea turtle, Northwest Atlantic Ocean DPS; Diazinon

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Point and non-point pollution.
- Marine debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action are not expected to negatively affect physical or biological features within nearshore designated critical habitat of Loggerhead Sea Turtle (NW Atlantic Ocean DPS). The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

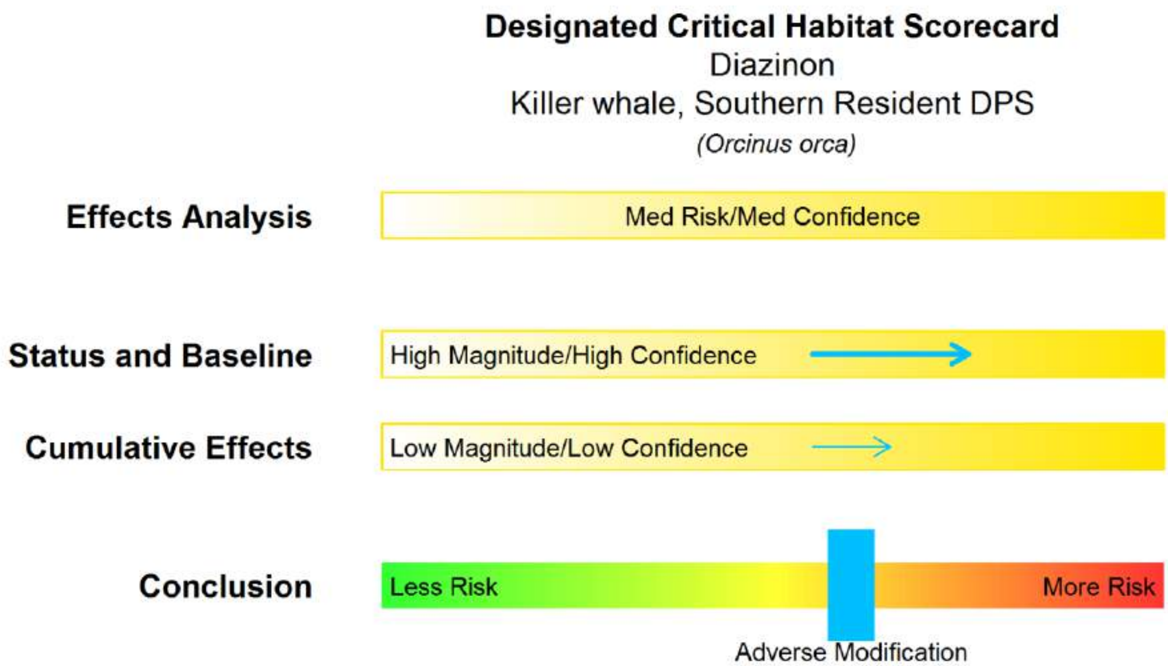

Figure 49. Designated Critical Habitat Scorecard; Killer whale, Southern Resident DPS; Diazinon

Effects Analysis: Medium risk/Medium confidence

- Reductions in prey species availability (i.e. recruiting into designated critical habitat) are likely to reduce the overall conservation value of designated critical habitat.
- We find medium confidence of medium risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Depleted prey throughout designated critical habitat.
- Point and non-point contaminants.
- Noise disturbance.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Altered hydrology and affects to prey brought about by climate change.
- Increased stresses (e.g., temperature) to freshwater habitats critical to prey.

Conclusion: We do not anticipate stressors of the action will directly affect physical and biological features (PBFs). Reductions in suitable prey and degradation of water quality are unlikely throughout designated critical habitat of Southern Resident Killer Whale from this action. However, indirectly, prey species (Chinook salmon) will be adversely affected by exposures anticipated in their freshwater habitats. The likelihood and magnitude of toxic effects will reduce the overall conservation value of designated critical habitat by reducing the recruitment and availability of this important prey. We find that the overall risk is medium and the confidence associated with that risk is medium over the 15-year duration of the action.

Diazinon is likely to adversely modify designated critical habitat: Adverse Modification

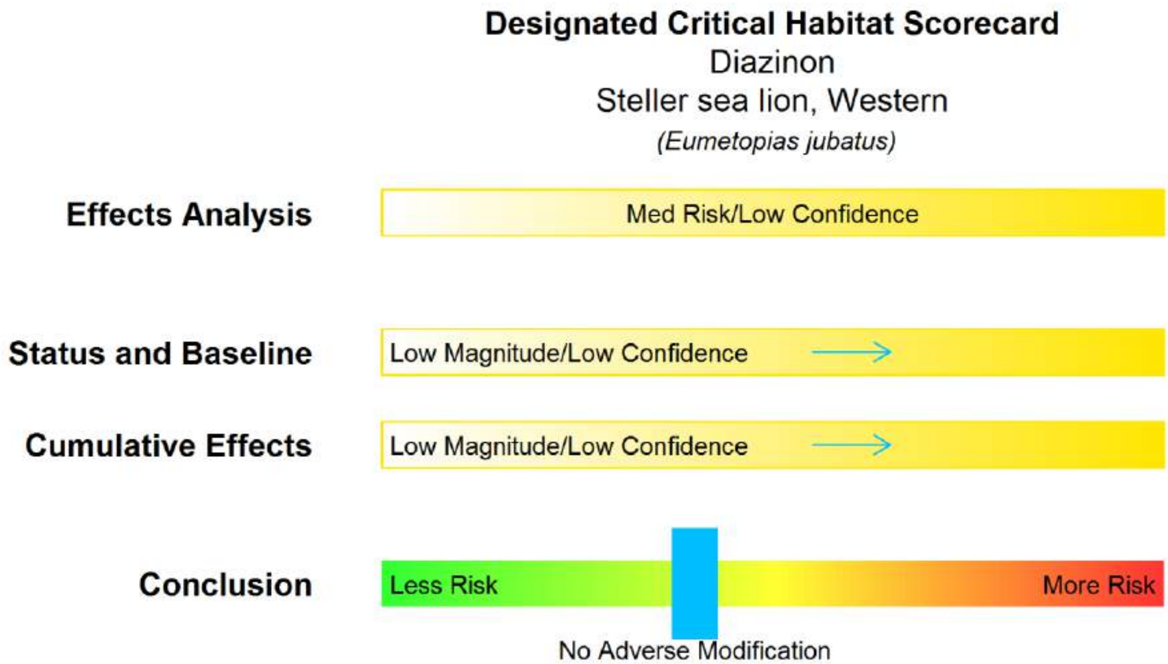

Figure 50. Designated Critical Habitat Scorecard; Steller sea lion, Western; Diazinon

<u>Effects Analysis: Medium risk/Low confidence</u>

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

<u>Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence</u>

- Point and non-point contaminants/pollution.
- Habitat degradation.
- Oil and gas exploration.

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction/activities may threaten PBFs.

<u>Conclusion:</u> The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of Steller Sea Lion (Western DPS). However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

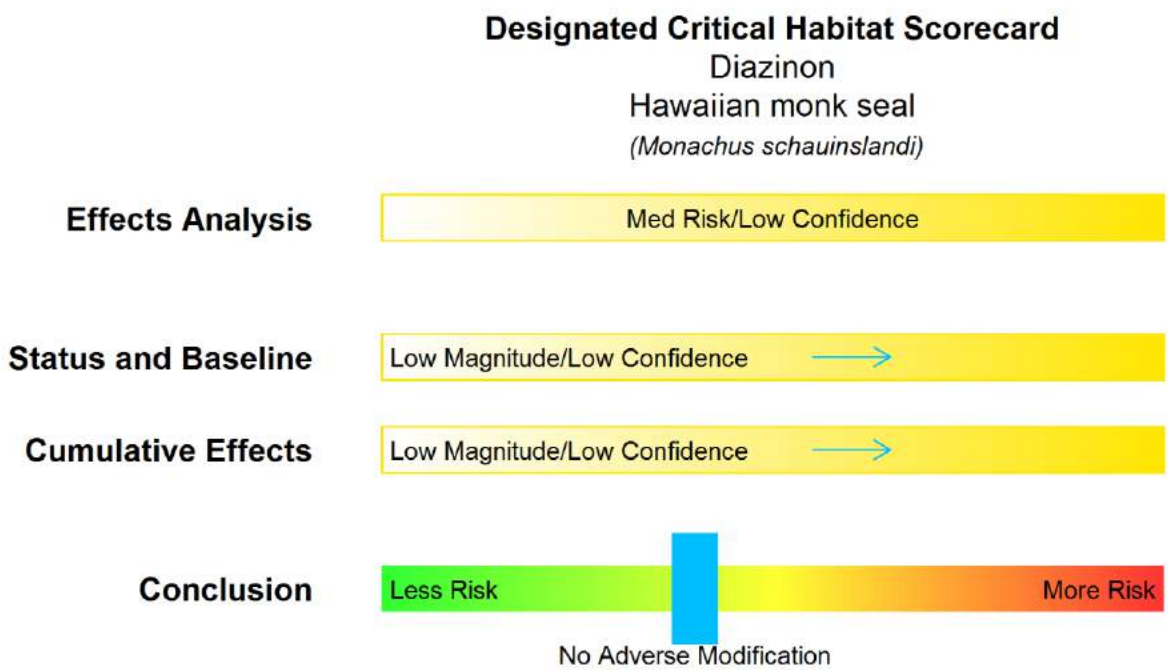

Figure 51. Designated Critical Habitat Scorecard; Hawaiian monk seal; Diazinon

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Limitations in food.
- Marine debris (entanglement).
- Habitat degradation.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction/activities may threaten PBFs.

Conclusion: The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of Hawaiian Monk Seal. However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of the marine portion of their designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

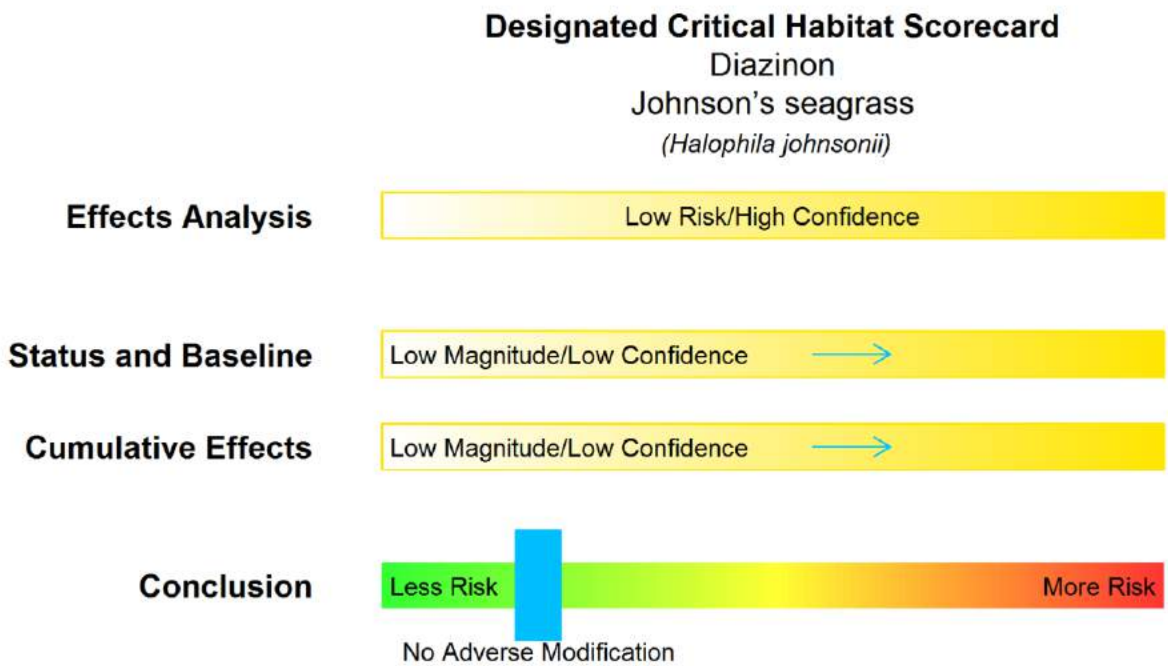

Figure 52. Designated Critical Habitat Scorecard; Johnson's seagrass; Diazinon

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in PBFs or reductions in the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted and PBFs identified.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Degraded water quality.
- Habitat destruction
- Siltation due to land-use practices.
- Algal overgrowth (nutrification).

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.

Conclusion: Water quality is a physical and biological features identified in Johnson's seagrass designated critical habitat. However, we do not anticipate exposures from the stressors of the action to be sufficient to reduce conservation values of this PBF. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Diazinon is not likely to adversely modify designated critical habitat: No Adverse Modification

CHAPTER 24

INTEGRATION AND SYNTHESIS FOR DESIGNATED CRITICAL HABITAT

MALATHION

TABLE OF CONTENTS

24 Malathion

24.1 Introduction

The integration and synthesis section is the final step in our assessment of the risk posed to species and critical habitat as a result of implementing the proposed action. In this section, we add the effects of the action to the environmental baseline and the cumulative effects to formulate the agency's biological opinion as to whether the proposed action is likely to: (1) reduce appreciably the likelihood of both the survival and recovery of an Endangered Species Act (ESA)-listed species in the wild by reducing its numbers, reproduction, or distribution; or (2) appreciably diminish the value of designated critical habitat for the conservation of an ESA-listed species. These assessments are made in full consideration of the status of the species.

We treat the information from the status of the species, environmental baseline, and cumulative effects, as "risk modifiers," in that the effects described in the effects analysis section may be modified by the condition of the species; the condition of environmental baseline, and the anticipated cumulative effects. The key questions addressed include:

- Status of Designated Critical Habitat:
  - Are the PBFs impaired or degraded?
- Environmental Baseline:
  - Are freshwater temperatures elevated?
  - Are pesticide environmental mixtures present, or anticipated based on current land use?
- Cumulative Effects:
  - Will future temperatures impair species aquatic habitats?
  - Will future hydrologic flows impair freshwater species habitats?
  - How might changes in ocean conditions affect the species habitat?

As detailed in the Environmental Baseline and Cumulative Effects chapters, adverse toxic responses to exposures to these OP pesticides are heightened with increases in temperature. In addition, exposures to other pesticides in the environment can cause additive or synergistic responses when simultaneously exposed to any of these OPs. Altered hydraulic flows can cause migratory blockages. Lower hydraulic flows can also result in increases in water temperatures and reductions in dissolved oxygen levels. These conditions can put stress on aquatic species and increases toxic responses when exposed to these pesticides.

Once each of the above sections is evaluated i.e., questions answered, the effects of the action and the risk modifiers are depicted graphically on a "scorecard." First, we assign a magnitude of influence (small or large) indicated graphically with one of two lengths of arrows. The shorter of the two arrows indicates a low magnitude, while the longer of the two arrows indicates a high magnitude as a risk modifier. The direction an arrow is pointed indicates the directionality of the risk modifier. For example, an environmental baseline arrow pointing towards more risk may indicate that environmental mixtures and elevated temperatures occur in the Environmental Baseline, which further stresses the species in question. We also assign a level of confidence in our selection of the small and large magnitude, indicated by a bold arrow (high confidence) or an un-bolded arrow (low confidence). The final arrow representing the influence on risk is graphically depicted on each of the designated critical habitat scorecards.

Figure 1. Example of arrows to represent direction, magnitude, and confidence of risk modifiers

Conclusion Section:

We combine the effects analysis conducted in chapters 15 – 17 with the baseline status of the species habitat, and cumulative effects to determine whether the action could reasonably be expected to appreciably diminish the conservation value of designated critical habitat. We state our conclusion as to whether the action is likely to destroy or adversely modify each of the species designated critical habitats.

A scorecard is generated for each species designated critical habitat. The effects of the proposed action is considered based on magnitude and confidence of the three arrows. Next, an adverse modification or no adverse modification vertical blue bar is placed on the horizontal risk bar i.e., the colored bar beginning with green (less risk) to red (more risk) (***Figure 2***) to depict our conclusion.

Figure 2: Example conclusion graphic

24.2 Designated Critical Habitat Scorecards (Malathion)

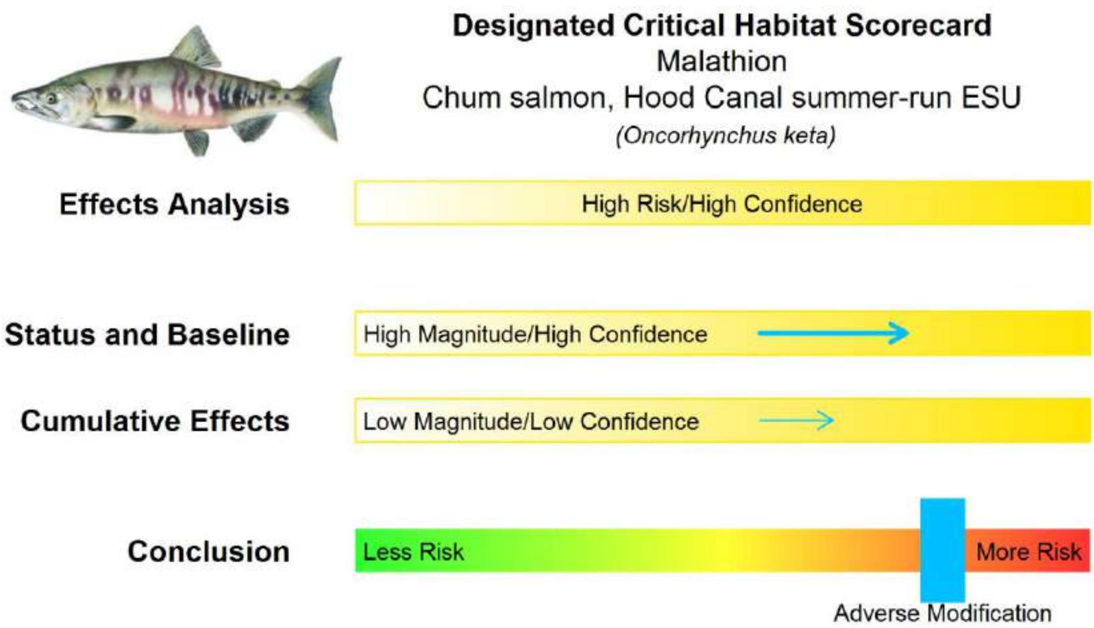

Figure 3. Designated Critical Habitat Scorecard; Chum salmon, Hood Canal summer-run Evolutionarily Significant Unit (ESU); Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Spawning and rearing PBFs are degraded
- Migration and rearing PBFs are impaired by loss of floodplain habitat necessary for juvenile growth and development
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- All 12 watersheds of high or medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 68,260 acres (over 3% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

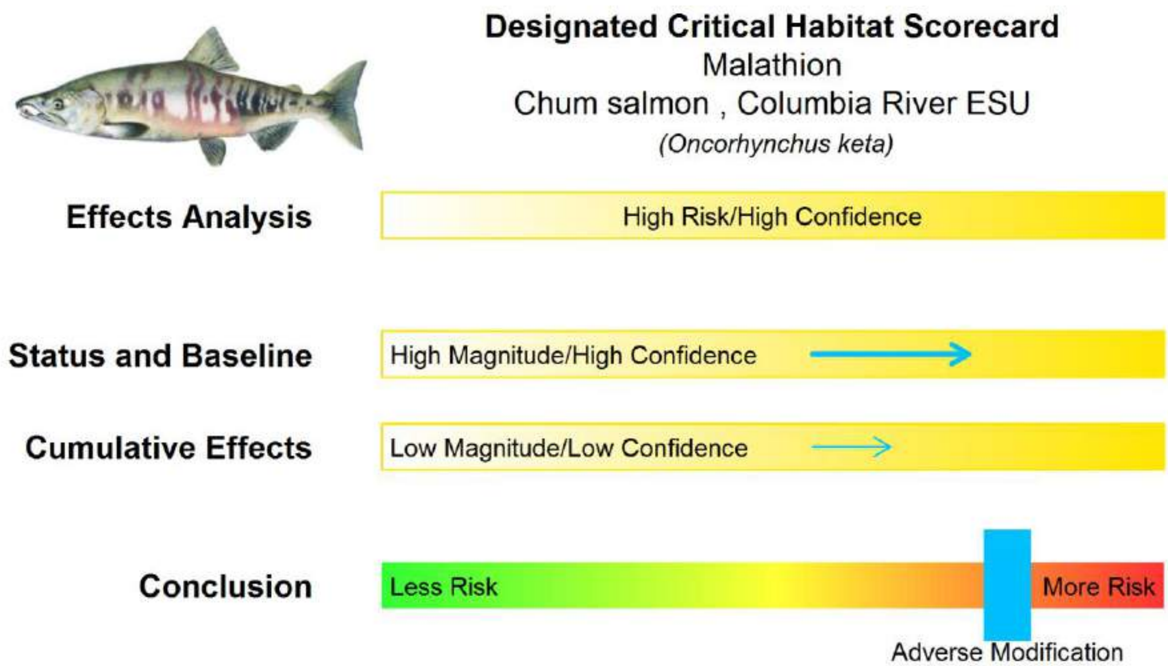

Figure 4. Designated Critical Habitat Scorecard; Chum salmon, Columbia River ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs (water quality and cover) are degraded
- Migration PBFs significantly impacted by dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- All 19 watersheds of high or medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 245,091 acres (over 8% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

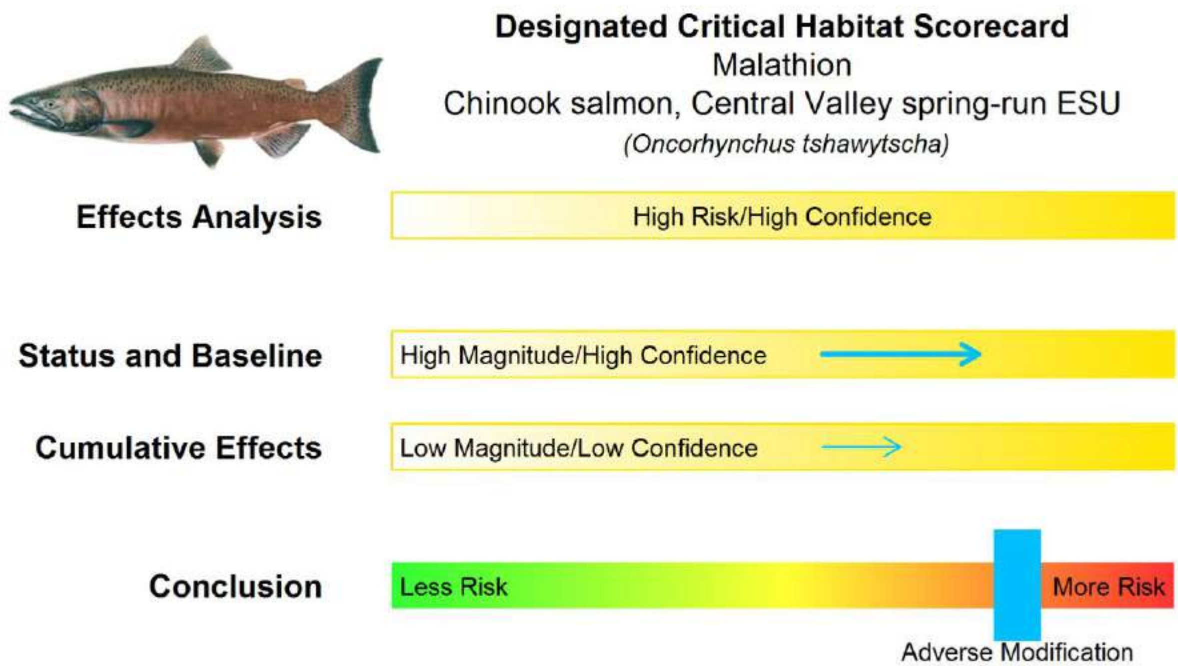

Figure 5. Designated Critical Habitat Scorecard; Chinook salmon, Central Valley spring-run ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by elevated temperatures, lost access to historic spawning sites, and loss of floodplain habitat
- Migration PBFs degraded by loss of cover and water diversions
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 38 watersheds, 28 are of high and 3 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 1,902,050 acres (over 58% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

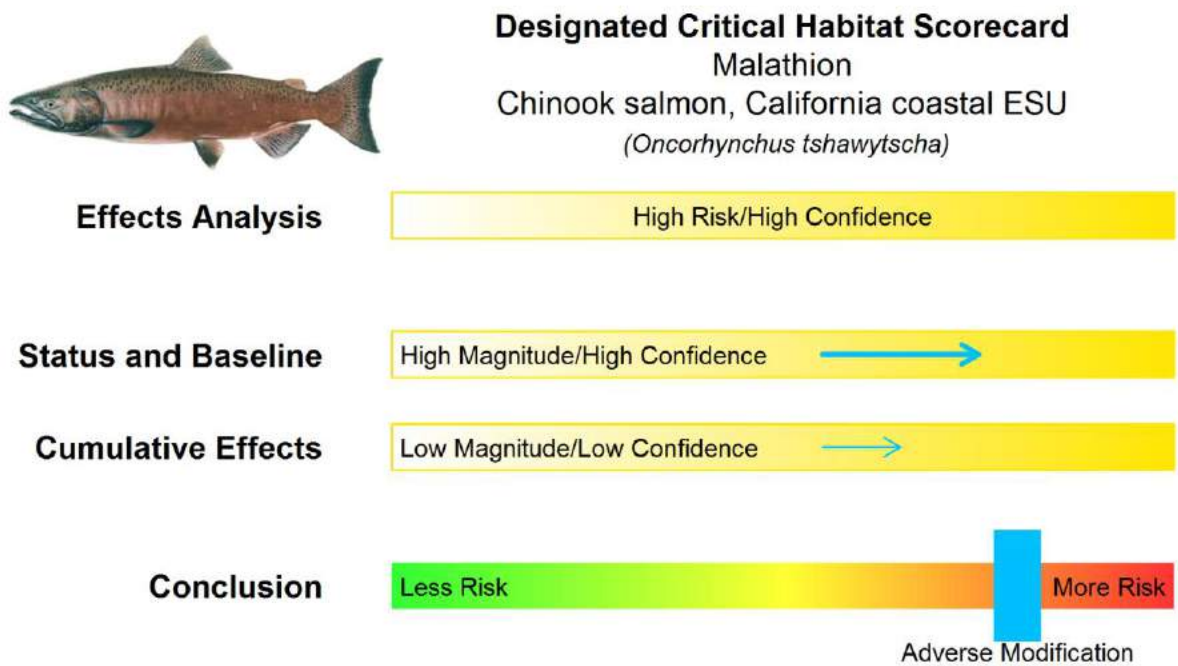

Figure 6. Designated Critical Habitat Scorecard; Chinook salmon, California coastal ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning PBFs are degraded by timber harvest
- Rearing and migration PBFs impacted by dams and invasive species.
- Estuarine PBFs degraded by water quality and saltwater mixing
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 45 watersheds, 27 are of high and 10 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Eleven use site categories, totaling more than 465,967 acres (over 13% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

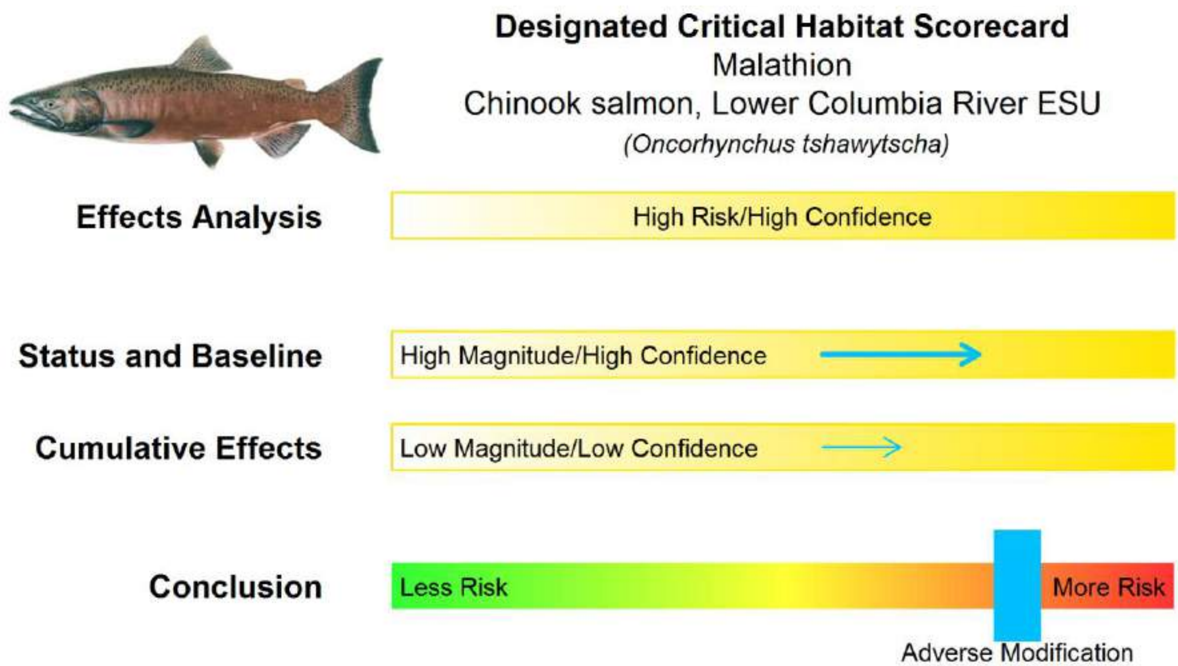

Figure 7. Designated Critical Habitat Scorecard; Chinook salmon, Lower Columbia River ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by timber harvest, agriculture, urbanization, loss of floodplain habitat, and reduced natural cover
- Migration PBFs impacted by dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of occupied watersheds, 31 are of high and 13 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 441,831 acres (over 13% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

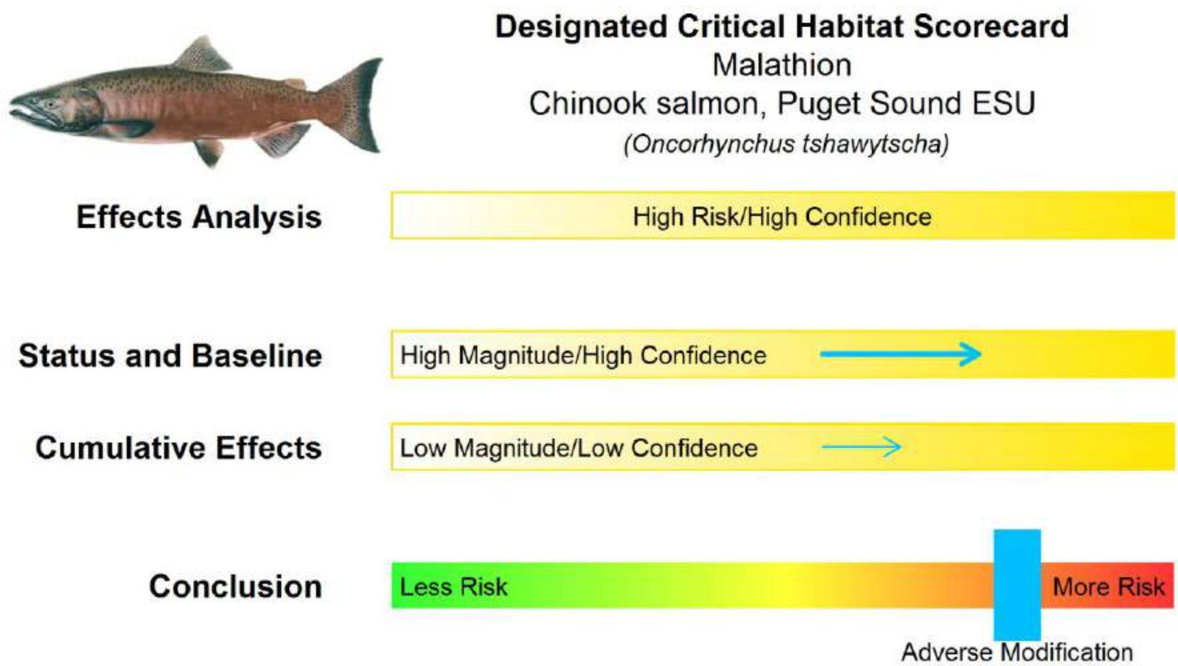

Figure 8. Designated Critical Habitat Scorecard; Chinook salmon, Puget Sound ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, rearing and migration PBFs are degraded by forestry, agriculture, urbanization, and loss of habitat
- Estuarine PBFs degraded by water quality, altered salinity, and lack of natural cover
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 61 watersheds, 40 are of high and 9 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 1,144,865 acres (over 12% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

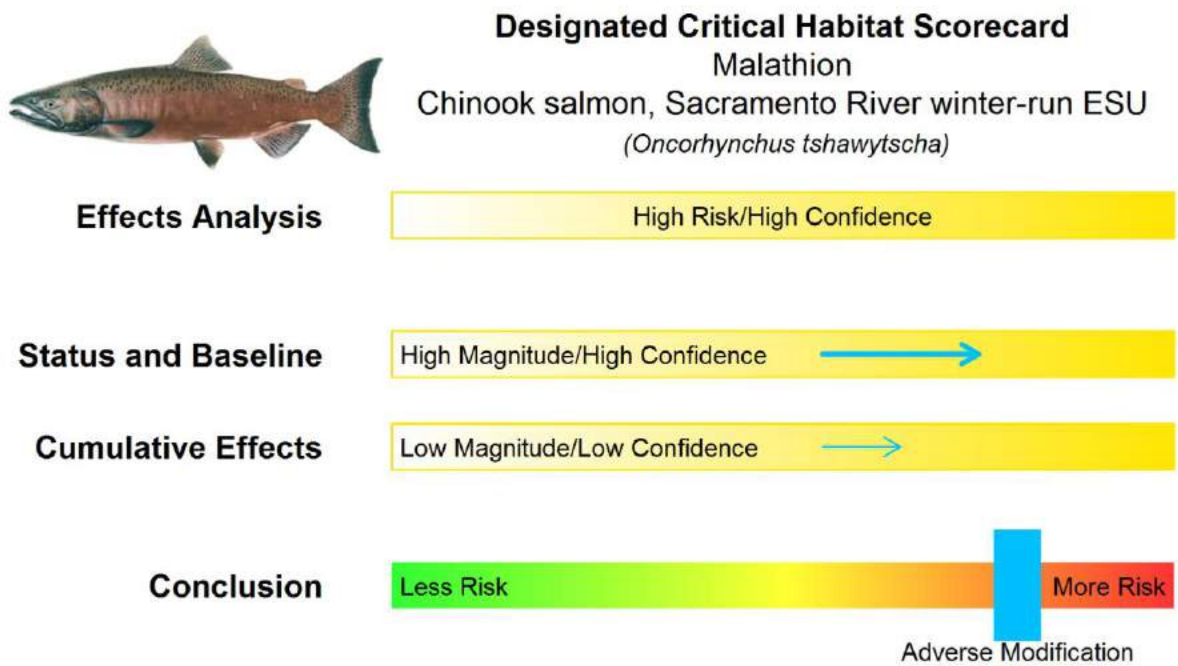

Figure 9. Designated Critical Habitat Scorecard; Chinook salmon, Sacramento River winter-run ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by elevated temperatures and loss of habitat
- Migration PBFs degraded by lack of natural cover and water diversions
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire Sacramento river and delta are considered of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 789,342 acres (over 53% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

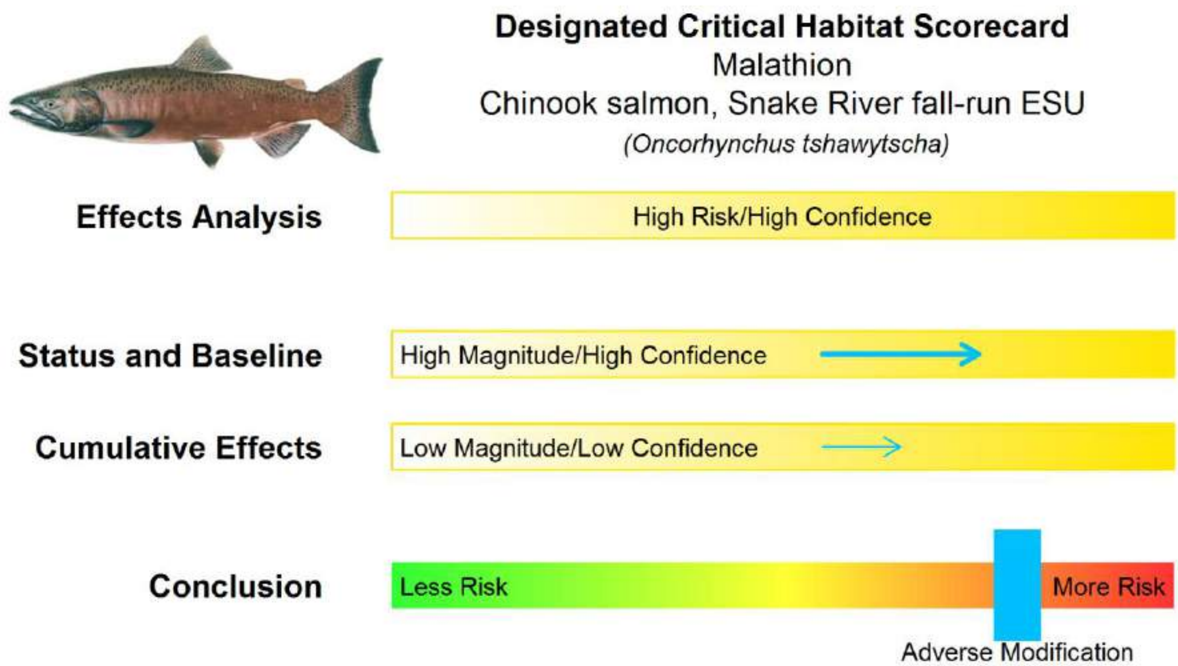

Figure 10. Designated Critical Habitat Scorecard; Chinook salmon, Snake River fall-run ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, rearing and migration PBFs are degraded by loss of habitat, impaired stream flows, barriers to fish passage, and poor water quality
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire river corridor is considered of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 3,440,270 acres (over 42% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

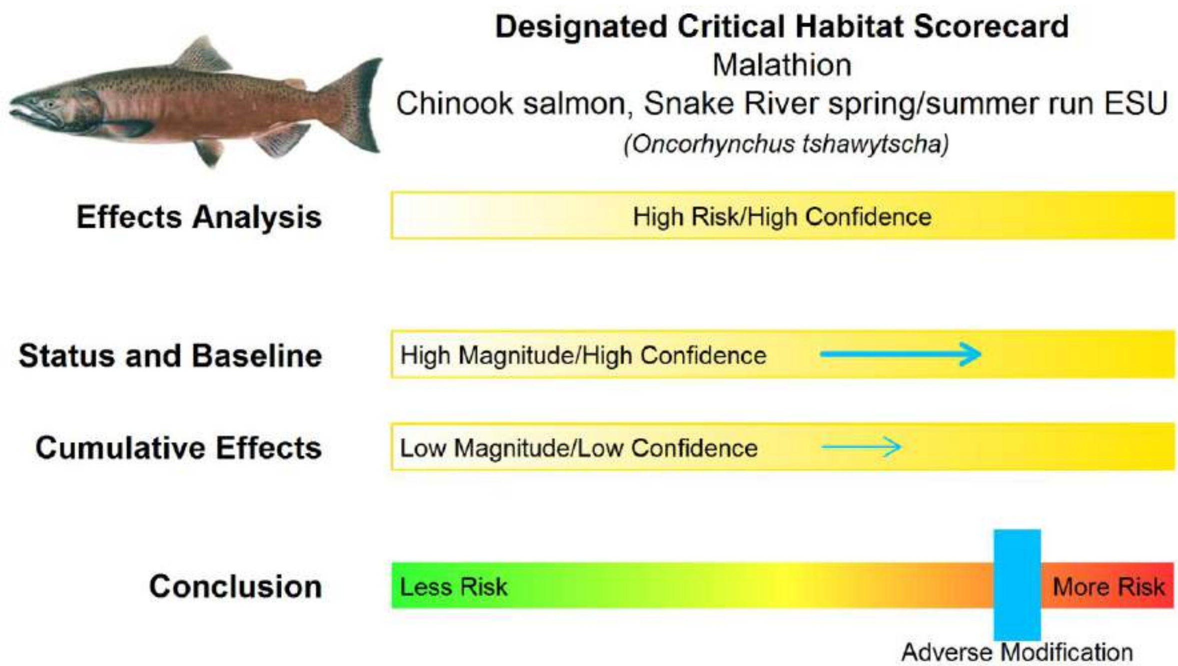

Figure 11. Designated Critical Habitat Scorecard; Chinook salmon, Snake River spring/summer run ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, rearing and migration PBFs are degraded by loss of habitat, altered stream flows, barriers to fish passage, dams, loss of cover, and poor water quality
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire river corridor is considered of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 17,435,837 acres (over 23% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

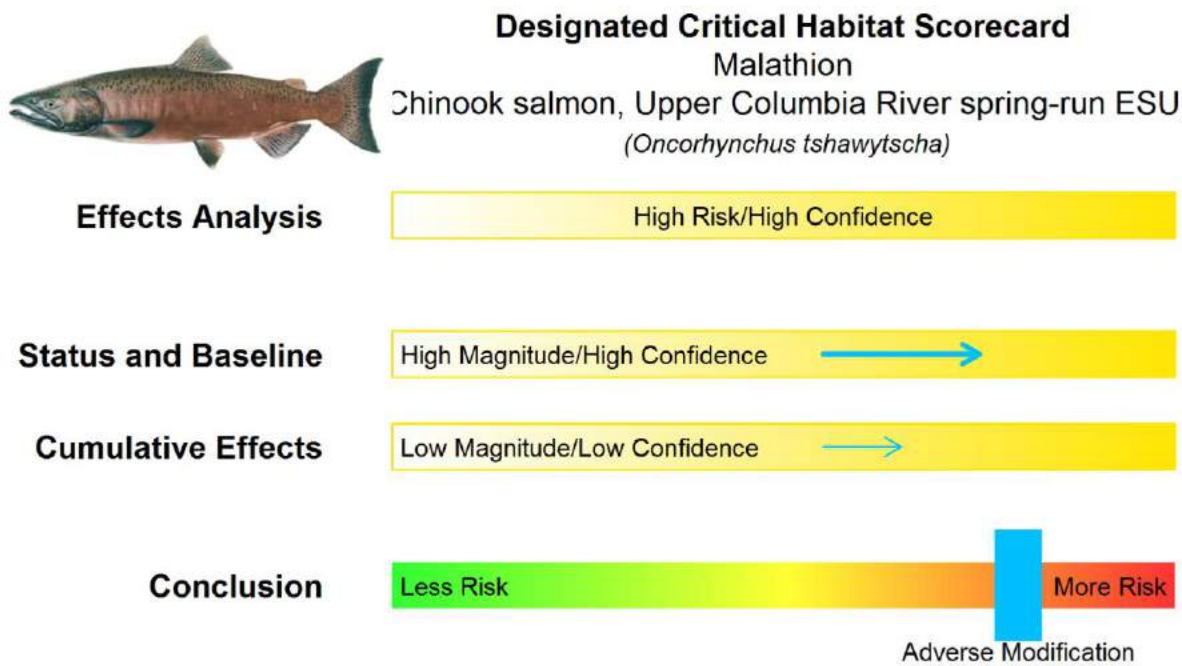

Figure 12. Designated Critical Habitat Scorecard; Chinook salmon, Upper Columbia River spring-run ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by urbanization and irrigation water diversions
- Migration PBFs degraded by numerous dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of occupied watersheds, 26 are of high and 5 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 660,759 acres (over 18% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

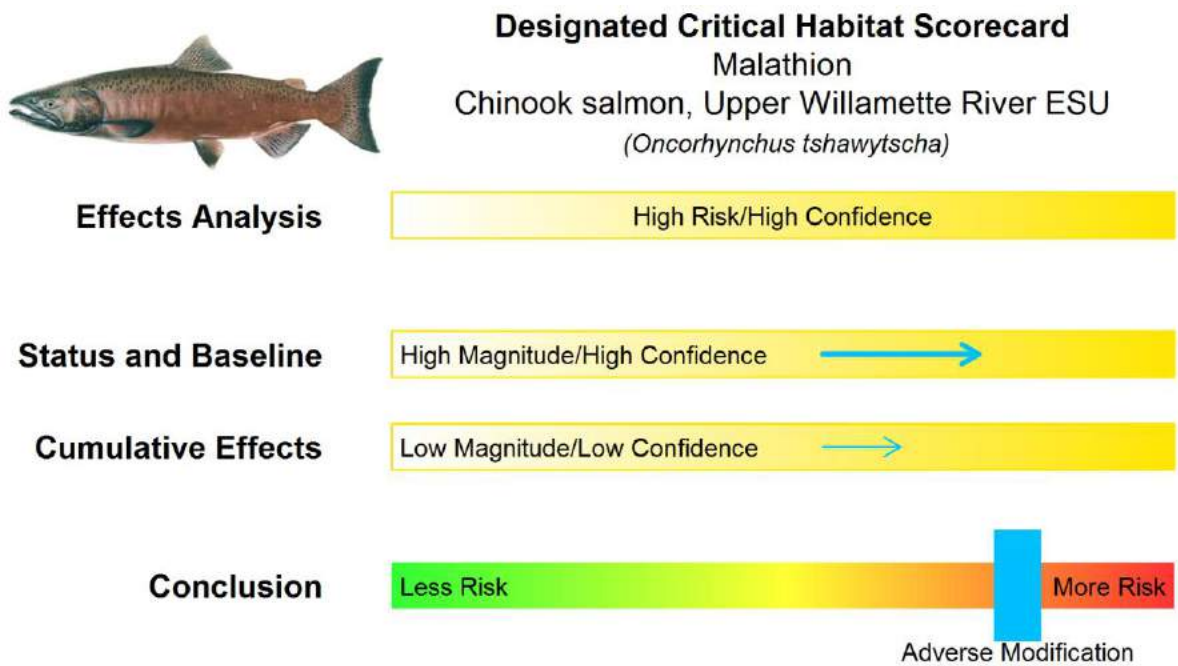

Figure 13. Designated Critical Habitat Scorecard; Chinook salmon, Upper Willamette River ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Migration, rearing, and estuary PBFs are degraded by dams, water management, loss of riparian vegetation, and quality of floodplain habitat
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 59 assessed watersheds, 22 are of high and 18 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 935,427 acres (over 28% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

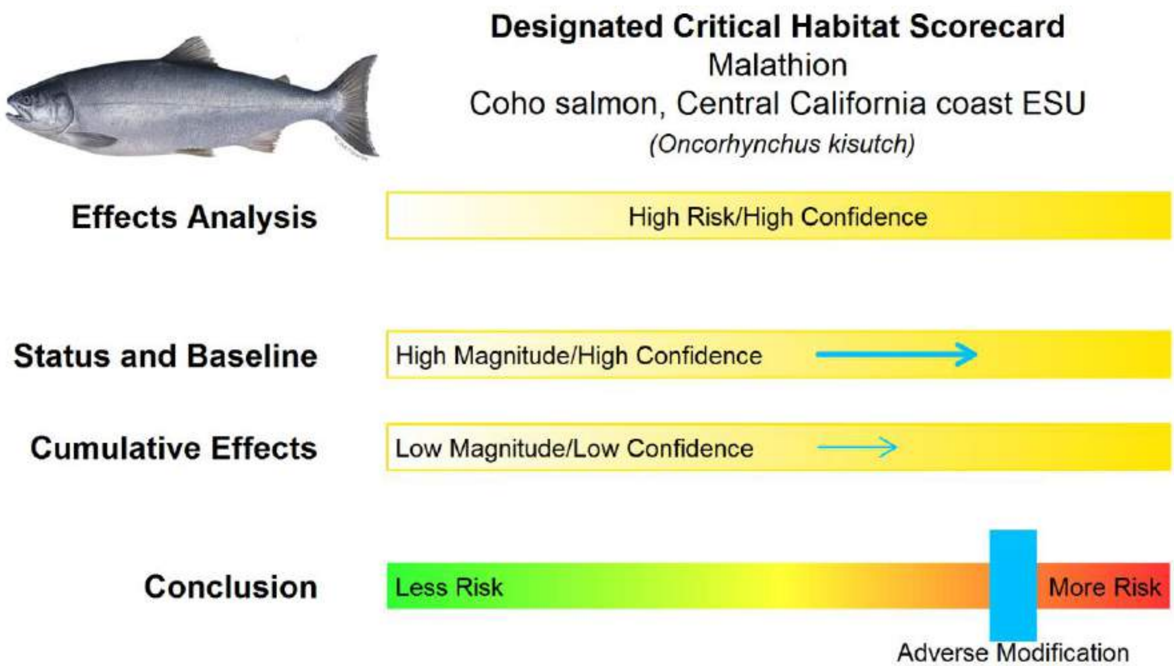

Figure 14. Designated Critical Habitat Scorecard; Coho salmon, Central California coast ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Degradation in quality and quantity of PBFs, especially in southern end of range
- Rearing PBFs degraded by loss of suitable incubation substrate and loss of habitat
- Elevated temperatures anticipated in freshwater habitats
- Environmental mixtures anticipated in freshwater habitats may impact PBFs

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 885,452 acres (over 23% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathions is likely to adversely modify designated critical habitat: Adverse Modification

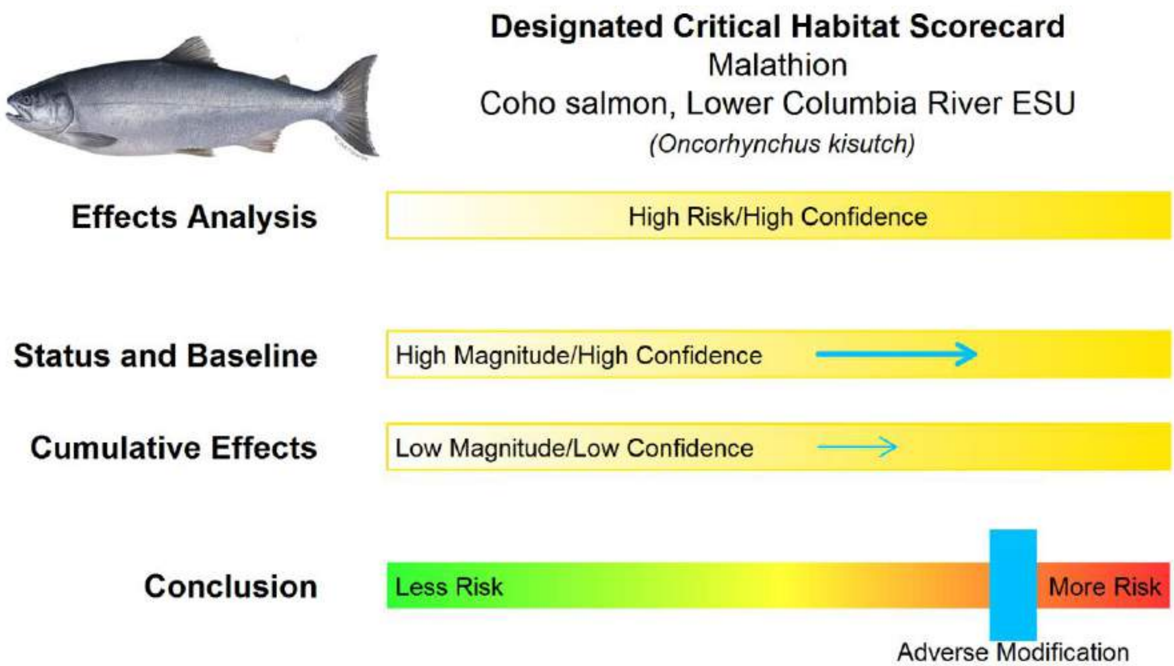

Figure 15. Designated Critical Habitat Scorecard; Coho salmon, Lower Columbia River ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by timber harvest, agriculture, urbanization, loss of floodplain habitat, and reduced natural cover
- Migration PBFs impacted by dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 603,588 acres (over 15% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

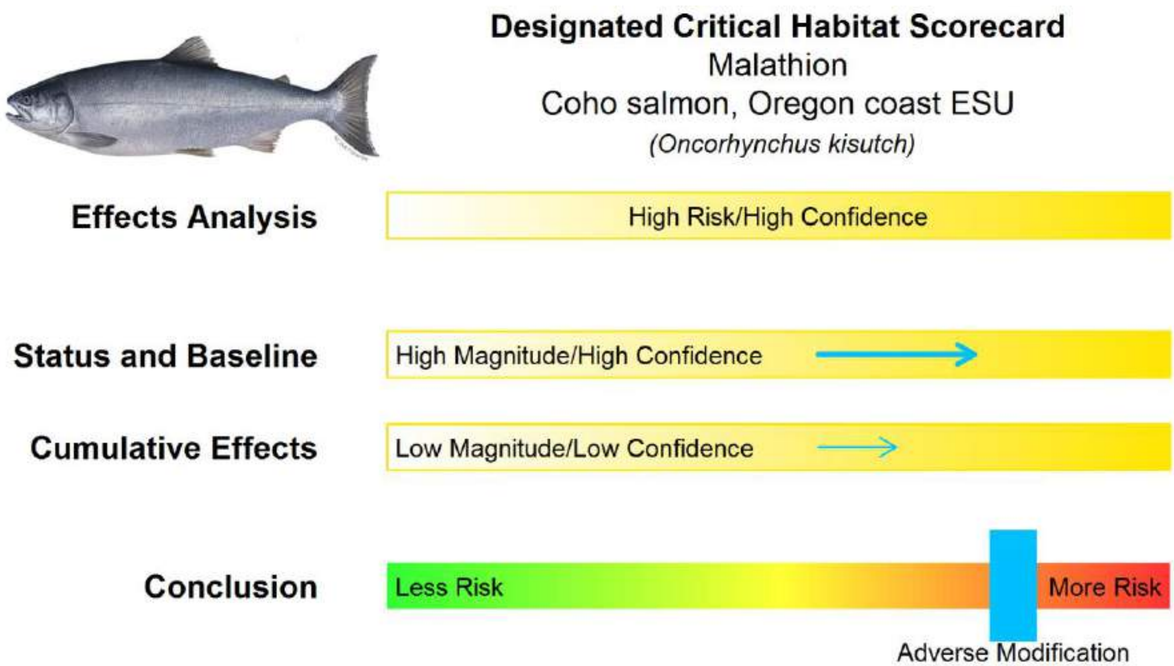

Figure 16. Designated Critical Habitat Scorecard; Coho salmon, Oregon coast ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Rearing PBFs are degraded by elevated water temperature
- All PBFs degraded by reduced water quality from contaminants and excess nutrients
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 80 assessed watersheds, 45 are of high and 27 are of medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 630,749 acres (over 11% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

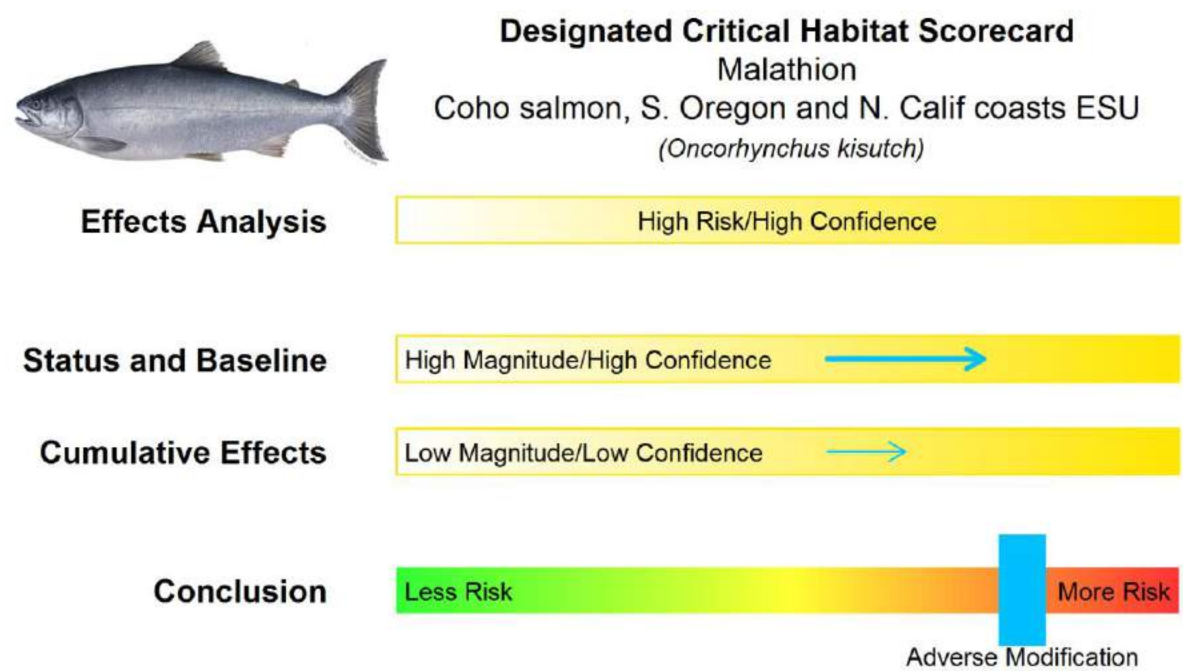

Figure 17. Designated Critical Habitat Scorecard; Coho salmon, S. Oregon and N. Calif coasts ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning PBFs are degraded by logging
- Rearing and migration PBFs degraded by loss of riparian vegetation and loss of floodplain habitat
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Eleven use site categories, totaling more than 1,037,089 acres (over 8% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

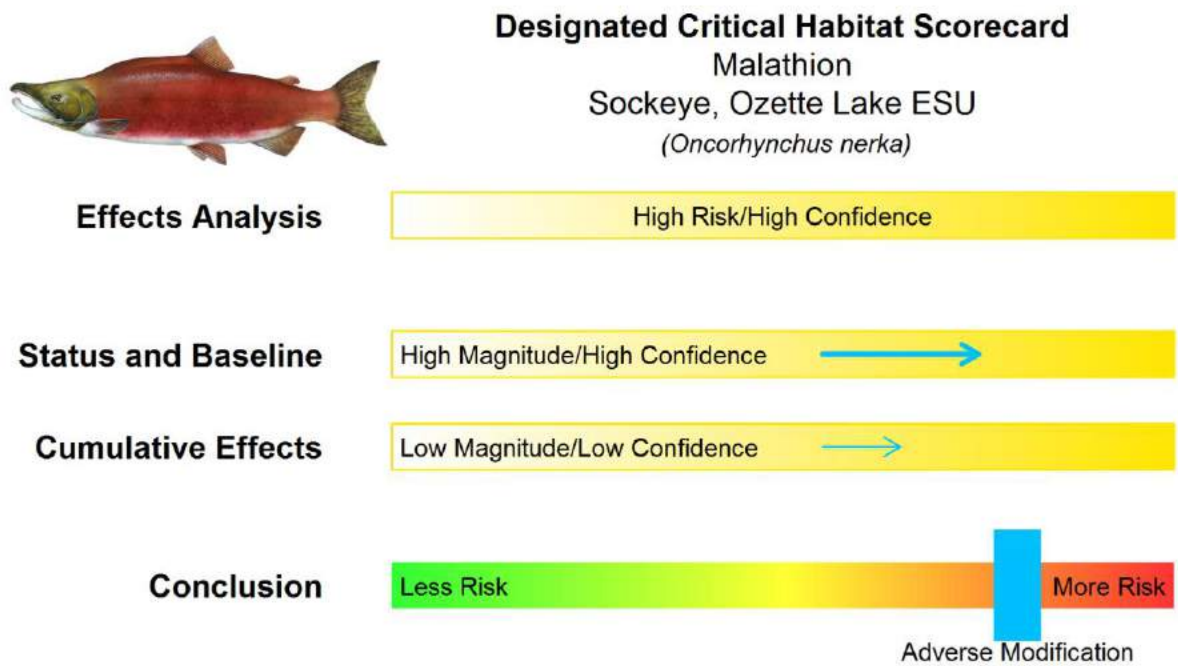

Figure 18. Designated Critical Habitat Scorecard; Sockeye, Ozette Lake ESU; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by excessive predation, invasive species, and loss of habitat
- Spawning and migration PBFs are degraded by low water levels, loss of suitable spawning habitat, and low summer water flows
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- The entire watershed is of high conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Three use site categories, totaling more than 1,678 acres (over 3% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

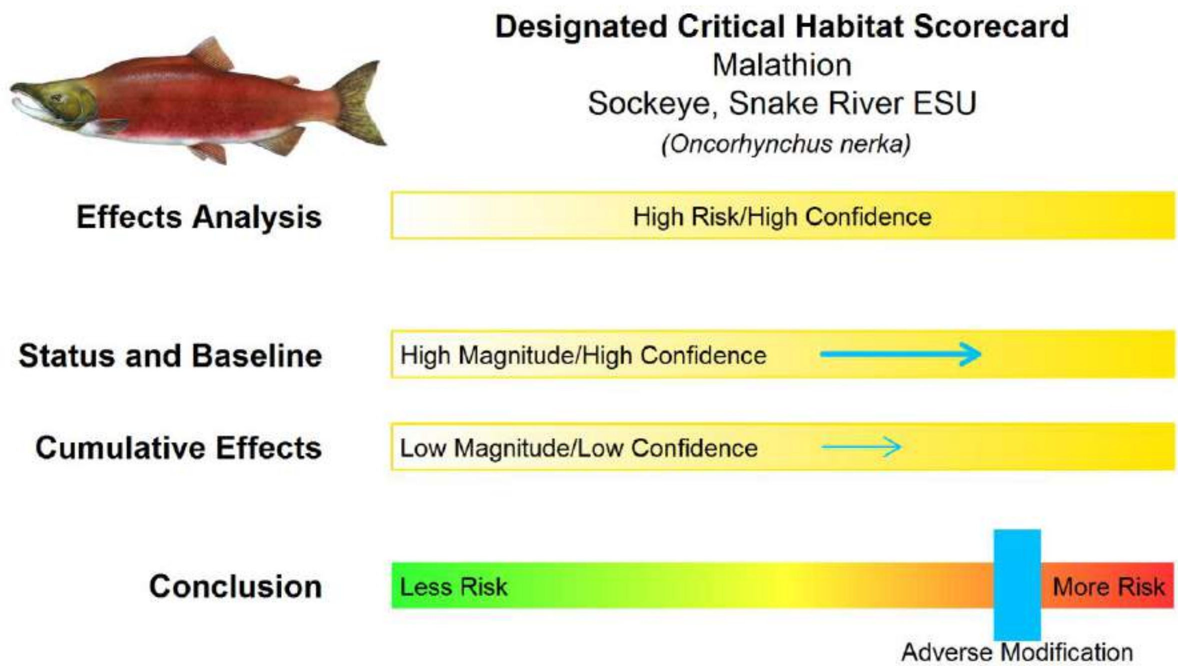

Figure 19. Designated Critical Habitat Scorecard; Sockeye, Snake River ESU; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Rearing and migration PBFs are degraded by impaired water quality from adjacent land uses
- Migration PBFs are degraded by multiple dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- All occupied and used areas of the watershed are of high conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 7,991,653 acres (over 24% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

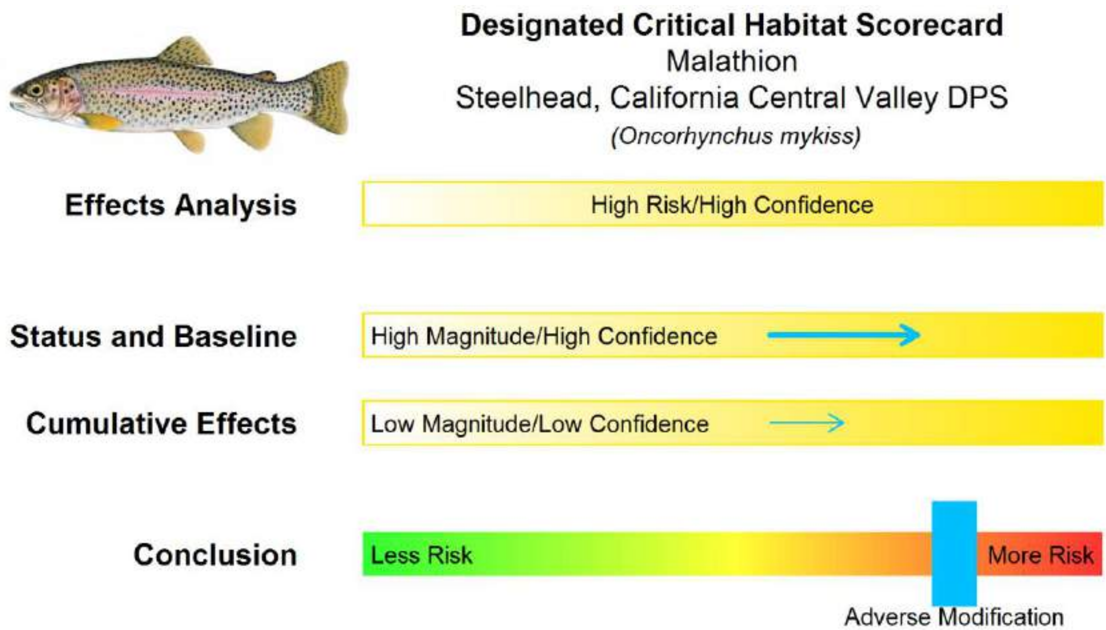

Figure 20. Designated Critical Habitat Scorecard; Steelhead, California Central Valley Distinct Population Segment (DPS); Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Spawning Physical and Biological Features (PBFs) are degraded by altered water flows and temperature
- Rearing and migration PBFs are degraded by altered riverine habitat, dense urbanization and agriculture, poor water quality, and water diversions
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 67 occupied watersheds, 37 are of high and 18 are of medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 3,306,149 acres (over 61% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

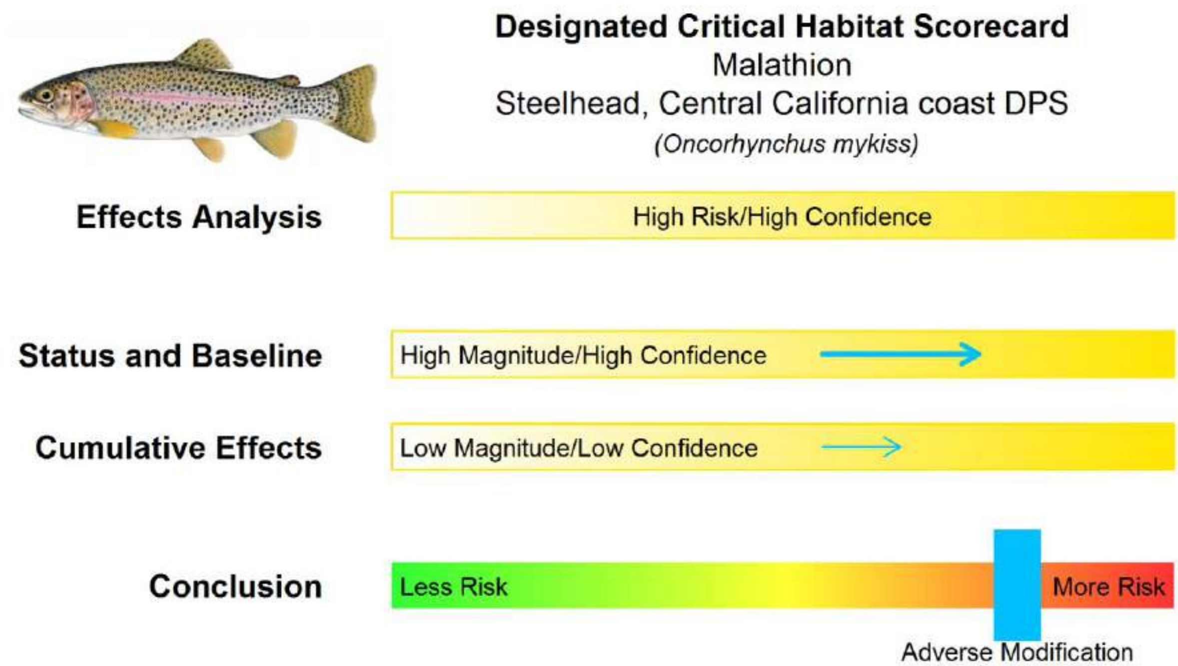

Figure 21. Designated Critical Habitat Scorecard; Steelhead, Central California coast DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning and rearing PBFs are degraded by sedimentation and elevated temperature
- All PBFs are degraded by loss of habitat, low summer flows, erosion, and contaminants
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 47 occupied watersheds, 19 are of high and 15 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 824,556 acres (over 28% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

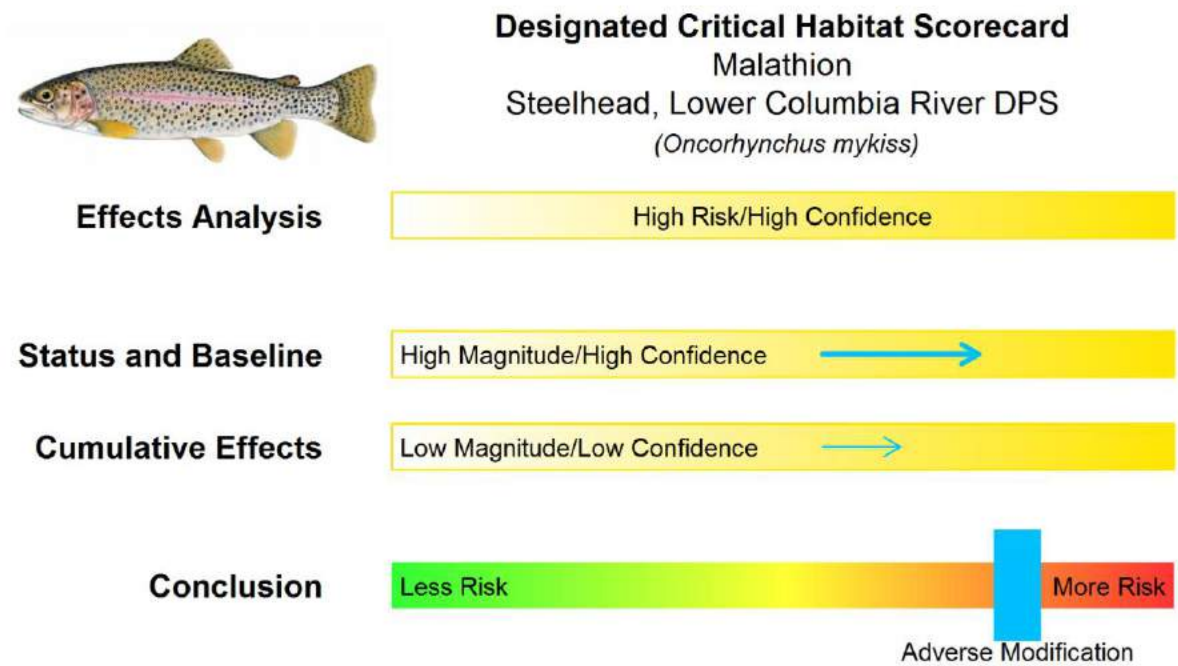

Figure 22. Designated Critical Habitat Scorecard; Steelhead, Lower Columbia River DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by agricultural runoff and lack of available prey
- Spawning, rearing and migration PBFs are degraded by timber harvests, dams, and loss of floodplain habitat
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 41 occupied watersheds, 28 are of high and 11 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 499,957 acres (over 8% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

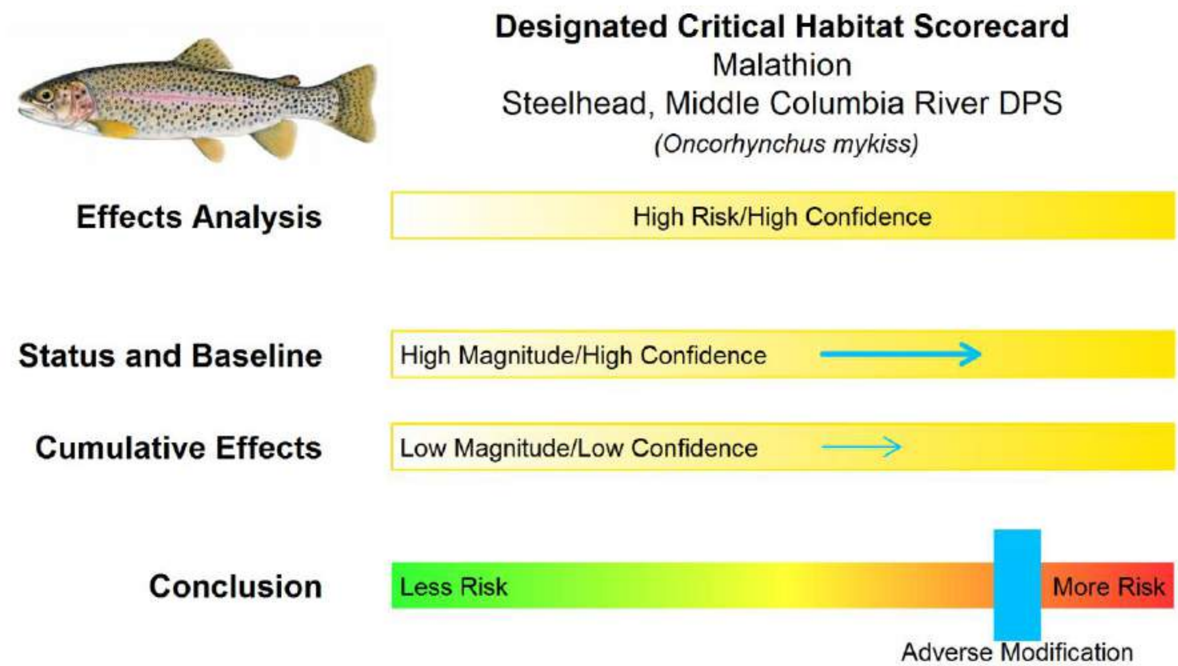

Figure 23. Designated Critical Habitat Scorecard; Steelhead, Middle Columbia River DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by water quality, reduced invertebrate prey, and loss of riparian vegetation
- Migration PBFs are degraded by several dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 106 assessed watersheds, 73 are of high and 24 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 2,483,713 acres (over 19% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

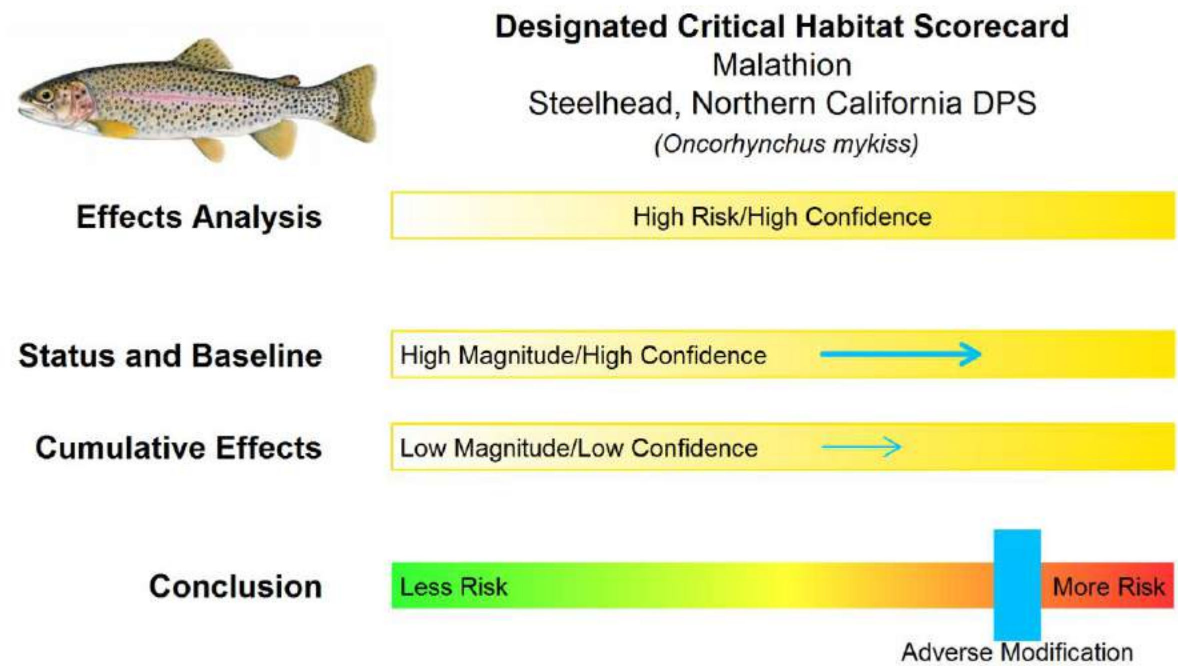

Figure 24. Designated Critical Habitat Scorecard; Steelhead, Northern California DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by loss of riparian vegetation and elevated temperature
- Spawning PBFs are degraded by lack of quality substrate and sedimentation
- Migration PBFs are degraded by bridges, culverts, and forest road construction
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 50 assessed watersheds, 27 are of high and 14 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Ten use site categories, totaling more than 413,593 acres (over 9% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

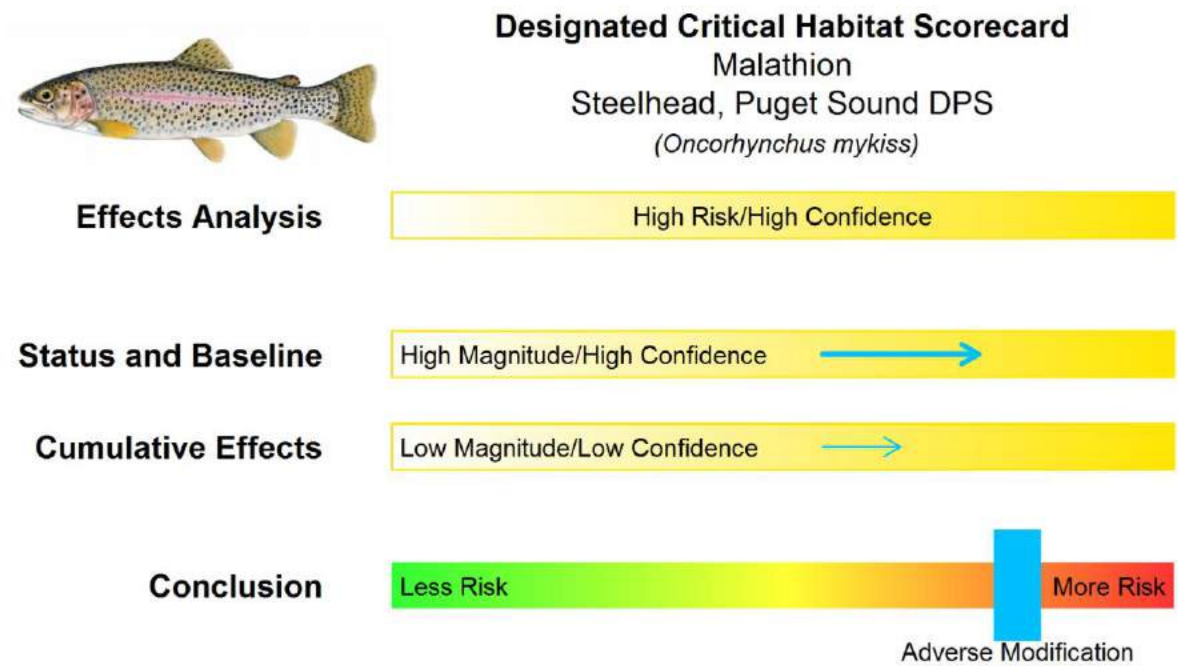

Figure 25. Designated Critical Habitat Scorecard; Steelhead, Puget Sound DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- Rearing, migration and spawning PBFs are degraded by forestry, agriculture, urbanization, loss of floodplain habitat, and poor water quality
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Most watersheds are of high or medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 7,137,589 acres (over 17% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

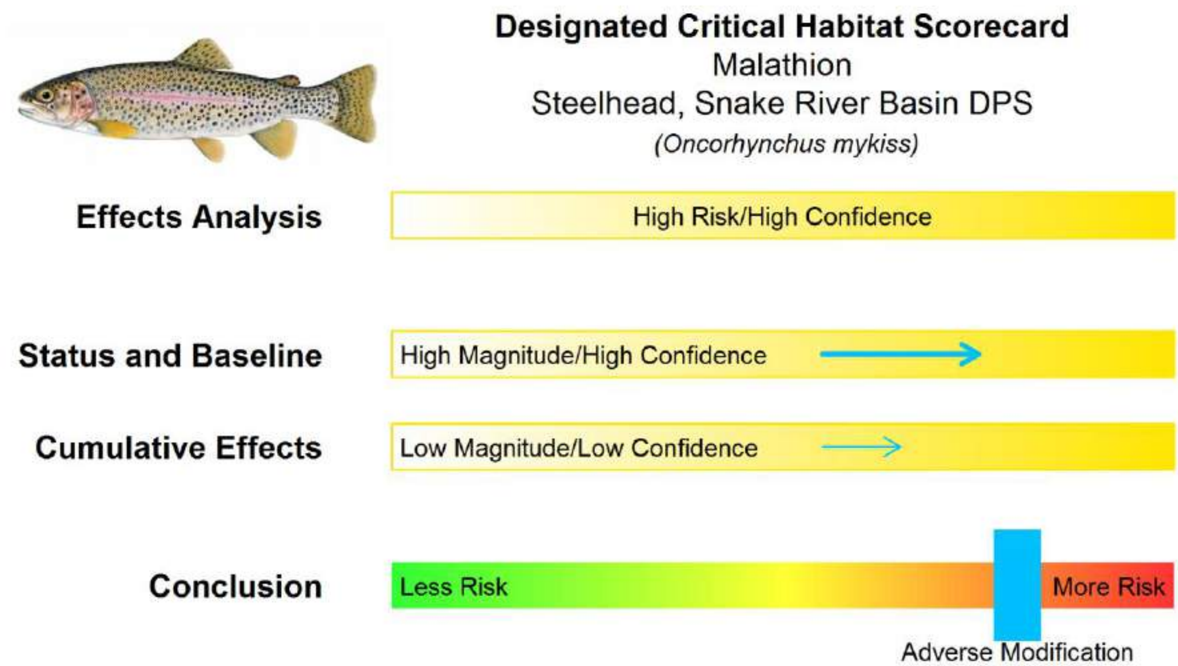

Figure 26. Designated Critical Habitat Scorecard; Steelhead, Snake River Basin DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by agricultural runoff, reduced invertebrate prey, loss of riparian vegetation, and elevated temperature
- Migration PBFs are degraded by several dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of assessed watersheds, 229 are of high and 41 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 3,622,139 acres (over 21% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

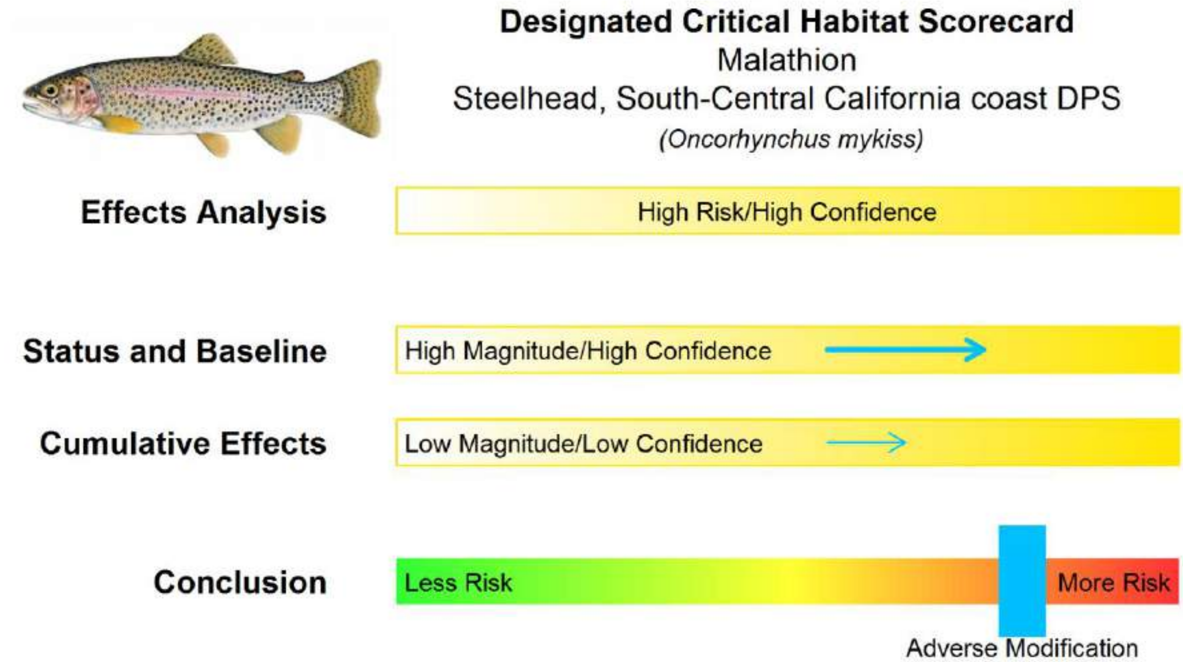

Figure 27. Designated Critical Habitat Scorecard; Steelhead, South-Central California coast DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing and migration PBFs are degraded by elevated temperatures and contaminants from urban and agricultural runoff
- Estuarine PBFs are degraded by altered habitat and contaminated runoff
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 29 occupied watersheds, 12 are of high and 11 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 1,149,507 acres (over 35% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

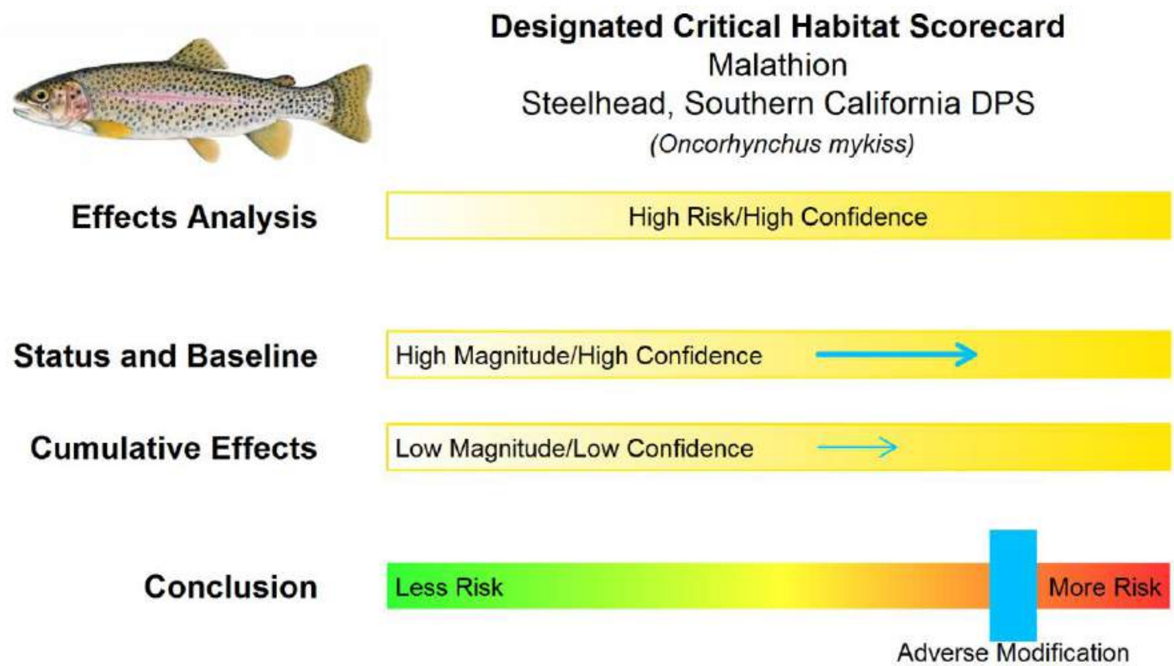

Figure 28. Designated Critical Habitat Scorecard; Steelhead, Southern California DPS; Malathion

<u>Effects Analysis: High risk/High confidence</u>

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

<u>Status and Baseline: Increased risk; High magnitude/High confidence</u>

- All PBFs are degraded by pollutants in urban and agricultural runoff, elevated temperatures, erosion, and low water flows
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 29 freshwater and estuarine watersheds, 21 are of high and 5 are of medium conservation value

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

<u>Conclusion:</u> We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Eleven use site categories, totaling more than 461,428 acres (over 22% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

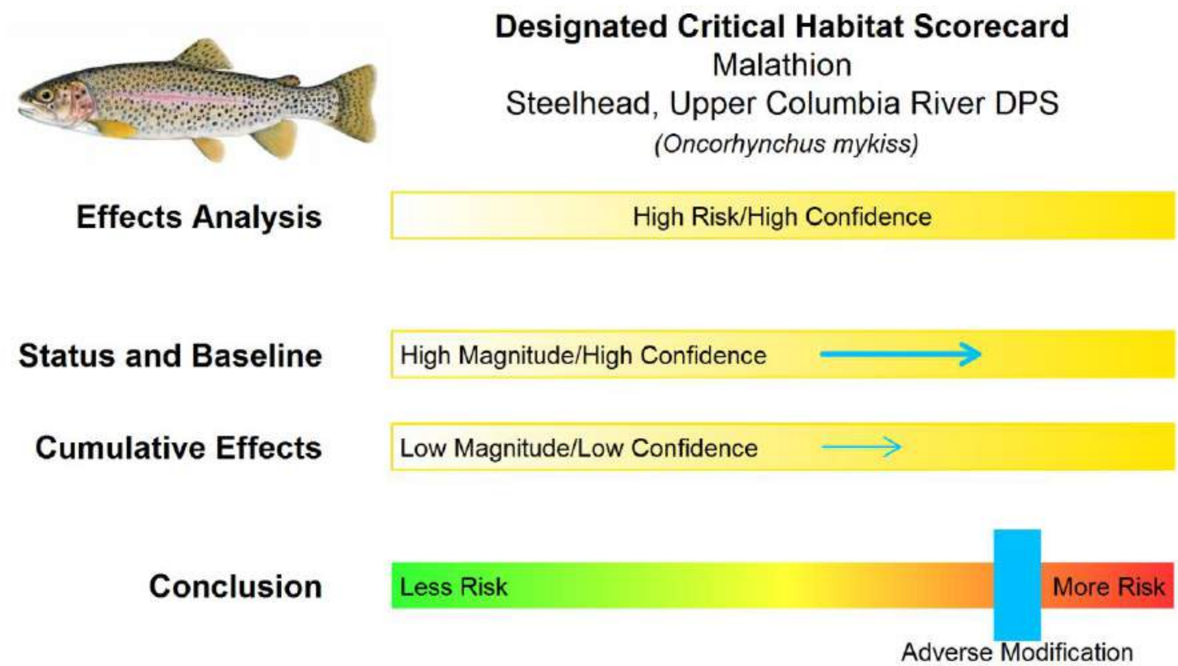

Figure 29. Designated Critical Habitat Scorecard; Steelhead, Upper Columbia River DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by agricultural runoff and lack of available prey
- Migration PBFs are degraded by several dams
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of 41 occupied watersheds, 31 are of high and 7 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 875,660 acres (over 20% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

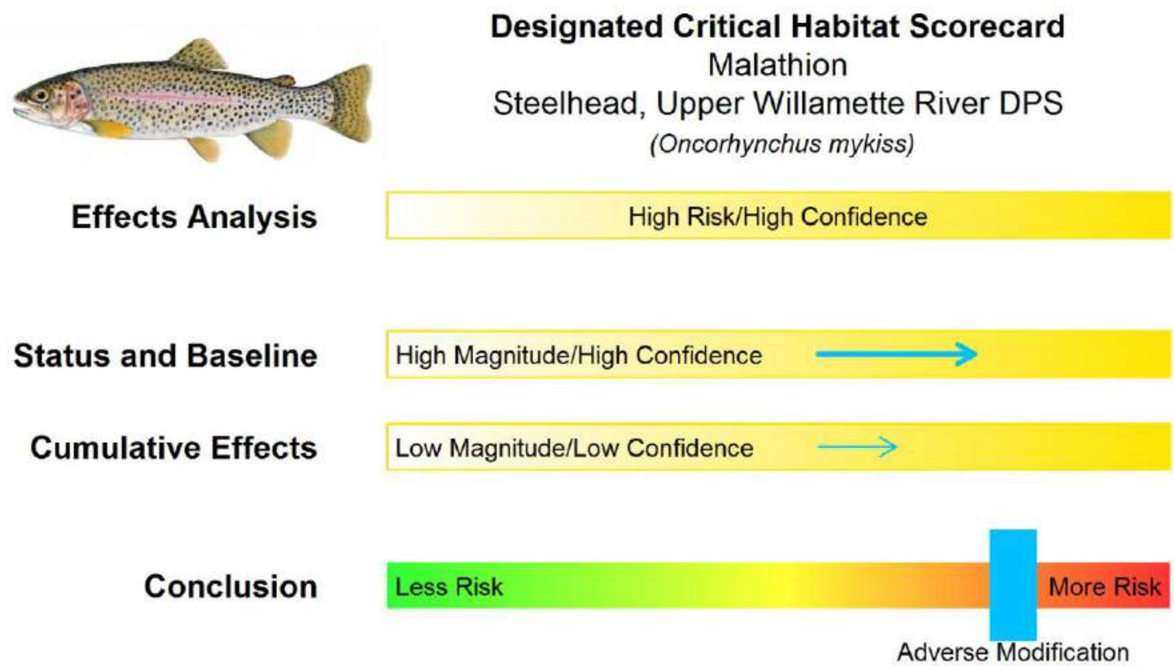

Figure 30. Designated Critical Habitat Scorecard; Steelhead, Upper Willamette River DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat
- Exposure to mixtures and elevated temperature expected to increase adverse effects
- We find high confidence of high risk due to expected exposures in freshwater habitats

Status and Baseline: Increased risk; High magnitude/High confidence

- Rearing PBFs are degraded by agricultural runoff and lack of available prey
- Migration PBFs are degraded by dams and elevated temperatures
- Elevated temperatures and environmental mixtures anticipated in freshwater habitats
- Of assessed watersheds, 14 are of high and 6 are of medium conservation value

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely; global climate change may threaten PBFs
- Anticipated hydrologic effects in freshwater areas may impact PBFs

Conclusion: We find high confidence of a high risk to this species' designated critical habitat. Critical habitat is most at risk in areas of extensive overlap with use sites. Twelve use site categories, totaling more than 982,770 acres (over 44% of critical habitat) currently overlap. Malathion may be applied anywhere in this critical habitat for mosquito control. Reductions in prey and degradation of water quality are anticipated to reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

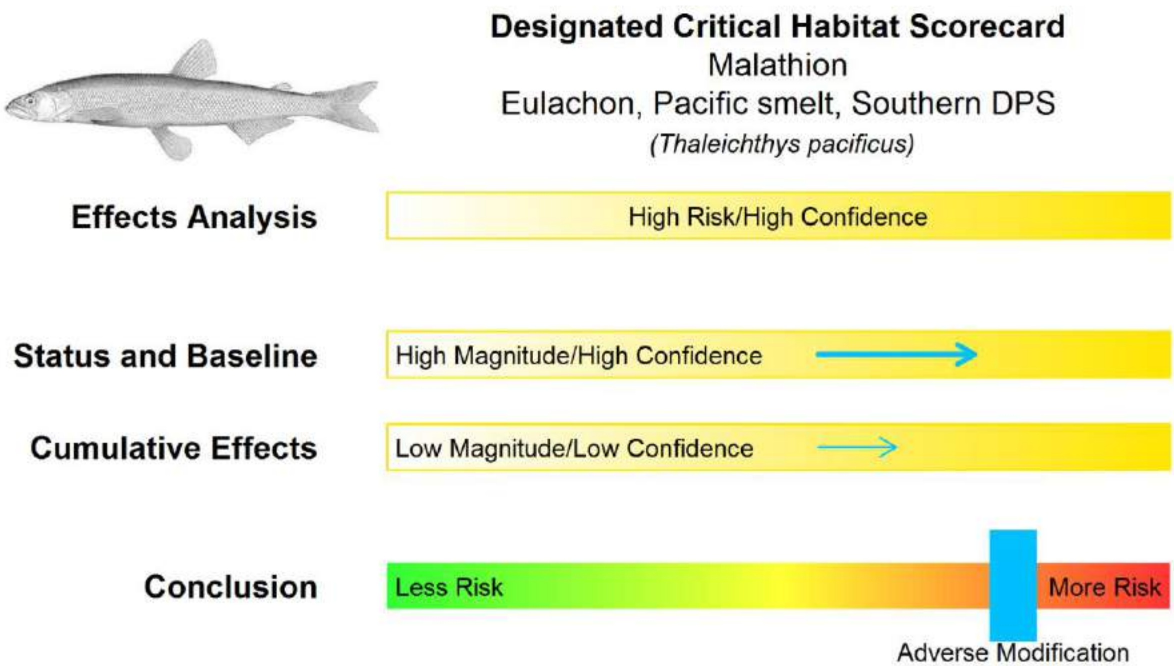

Figure 31. Designated Critical Habitat Scorecard; Eulachon, Pacific smelt, Southern DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Spawning, incubation, and rearing PBFs are degraded.
- Dams block flow and access to historical spawning grounds and are cause for degraded spawning substrates below.
- Elevated temperatures prevalent in freshwater habitats.
- Environmental mixtures anticipated in freshwater habitats may affect prey.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten eulachon, particularly in the southern portion of their range where ocean warming trends may be the most pronounced and may alter prey, spawning, and rearing success.
- Anticipated hydrologic changes in freshwater areas may affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Malathion may be applied anywhere in eulachon critical habitat for mosquito control. Twelve use site categories, totaling more than 99,572 acres (over 6 percent of acres) are currently present. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

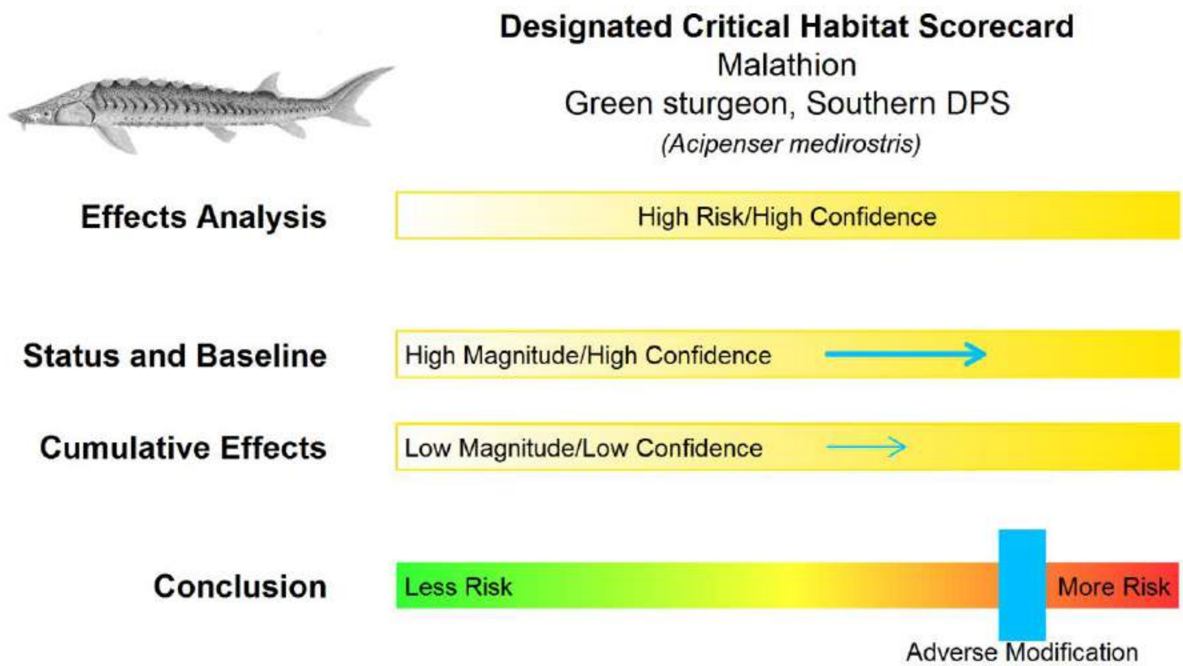

Figure 32. Designated Critical Habitat Scorecard; Green sturgeon, Southern DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Insufficient freshwater flow rates in spawning areas.
- Contaminants (e.g., pesticides) prevalent in freshwater habitat.
- Impassable barriers limit spawning to limited sections in Sacramento River.
- Elevated water temperatures persist in freshwater.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Elevated temperatures likely to remain. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Malathion may be applied anywhere in eulachon critical habitat for mosquito control. Thirteen use site categories, totaling more than 2,829,232 acres (over 28 percent of acres) are currently present. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

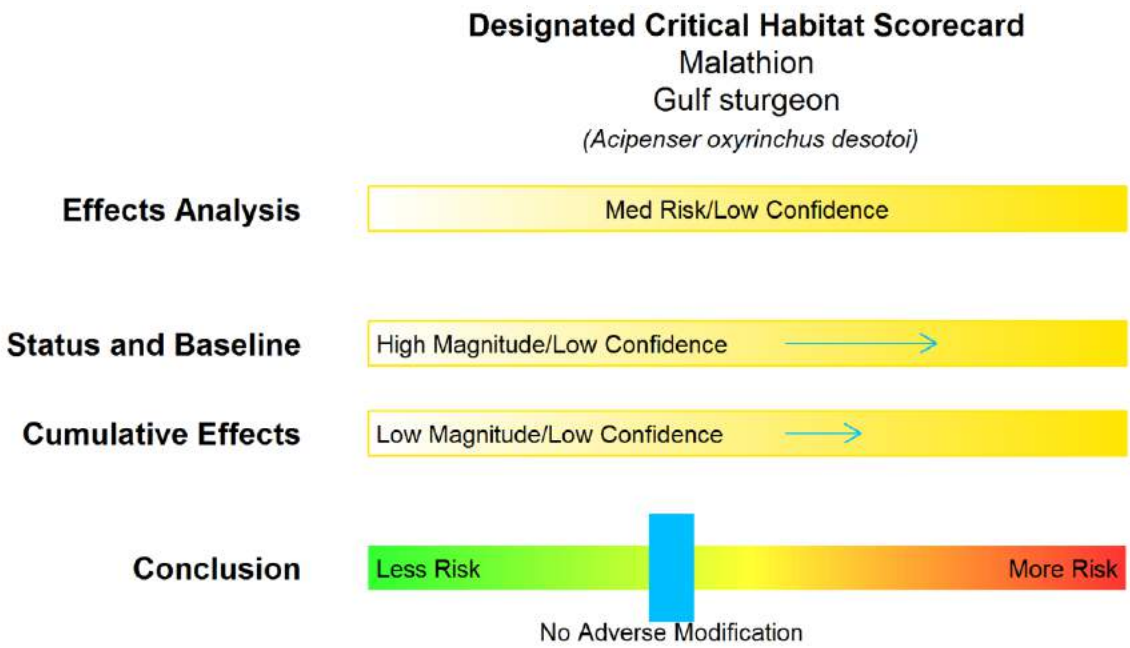

Figure 33. Designated Critical Habitat Scorecard; Gulf sturgeon; Malathion

<u>Effects Analysis: Medium risk/Low confidence</u>

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted in their marine habitats.

<u>Status and Baseline: Increased risk; High magnitude/Low confidence</u>

- Construction of water control structures, such as dams and sills exacerbated habitat loss.
- Dredging.
- Groundwater extraction, irrigation, and altered flows.
- Poor water quality.
- Contaminants, primarily from industrial sources.

<u>Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence</u>

- Global climate change may threaten PBFs.

<u>Conclusion:</u> We have low confidence in EECs predicted for the marine habitats. We find that the overall risk is medium and the confidence associated with that risk is low. We do not anticipate reductions in prey and degradation of water quality will reduce conservation values throughout the marine portion of this species designated critical habitat over the 15-year action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

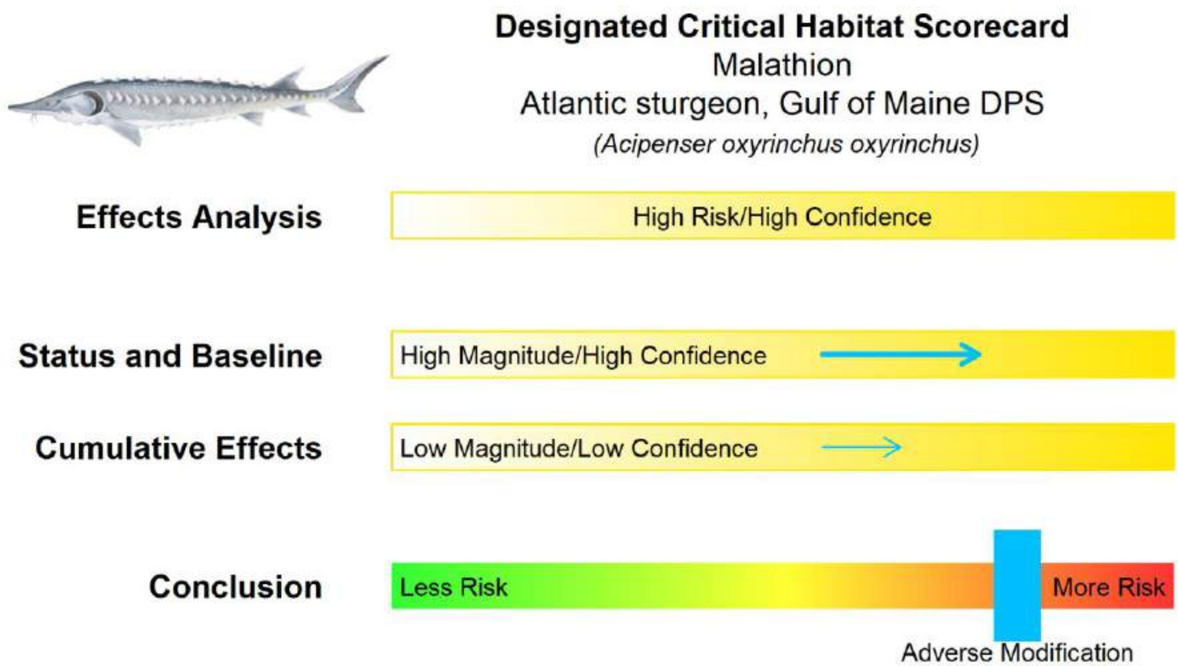

Figure 34. Designated Critical Habitat Scorecard; Atlantic sturgeon, Gulf of Maine DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Malathion may be applied anywhere in this species critical habitat for mosquito control. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

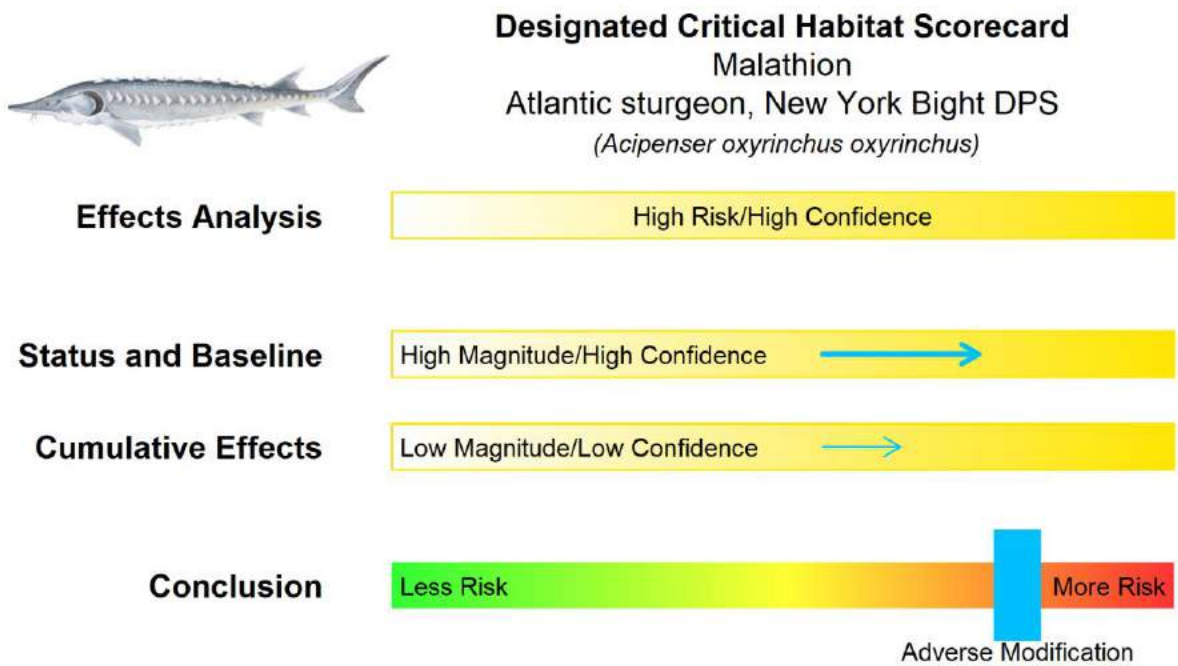

Figure 35. Designated Critical Habitat Scorecard; Atlantic sturgeon, New York Bight DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Malathion may be applied anywhere in this species critical habitat for mosquito control. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

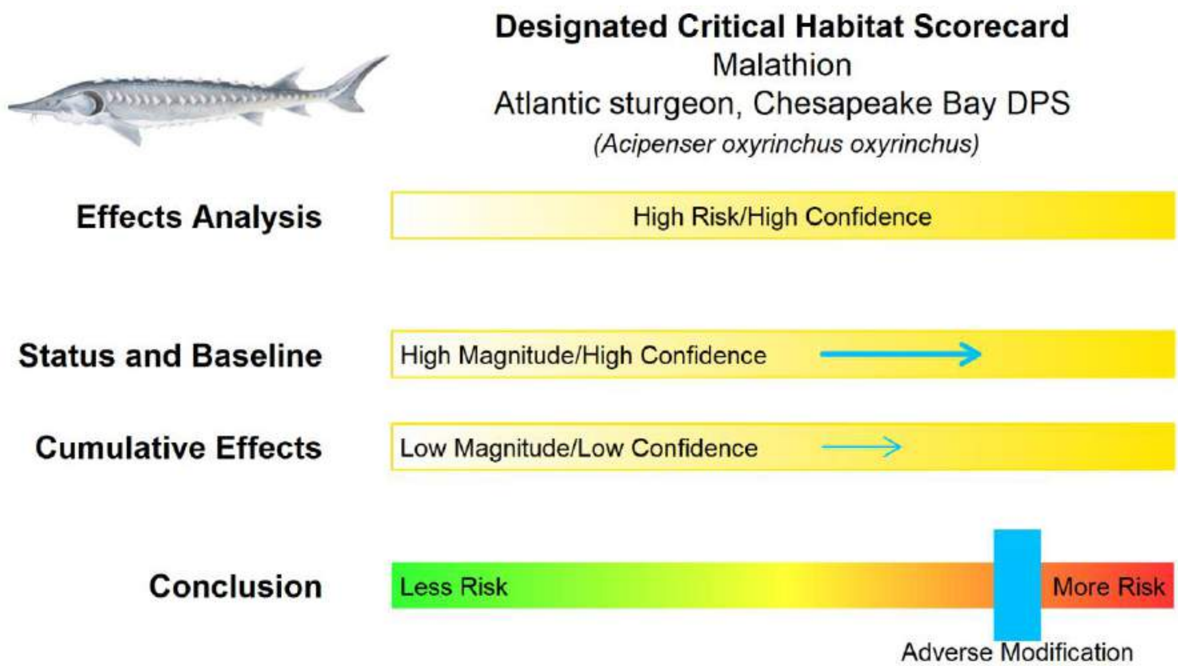

Figure 36. Designated Critical Habitat Scorecard; Atlantic sturgeon, Chesapeake Bay DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Malathion may be applied anywhere in this species critical habitat for mosquito control. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

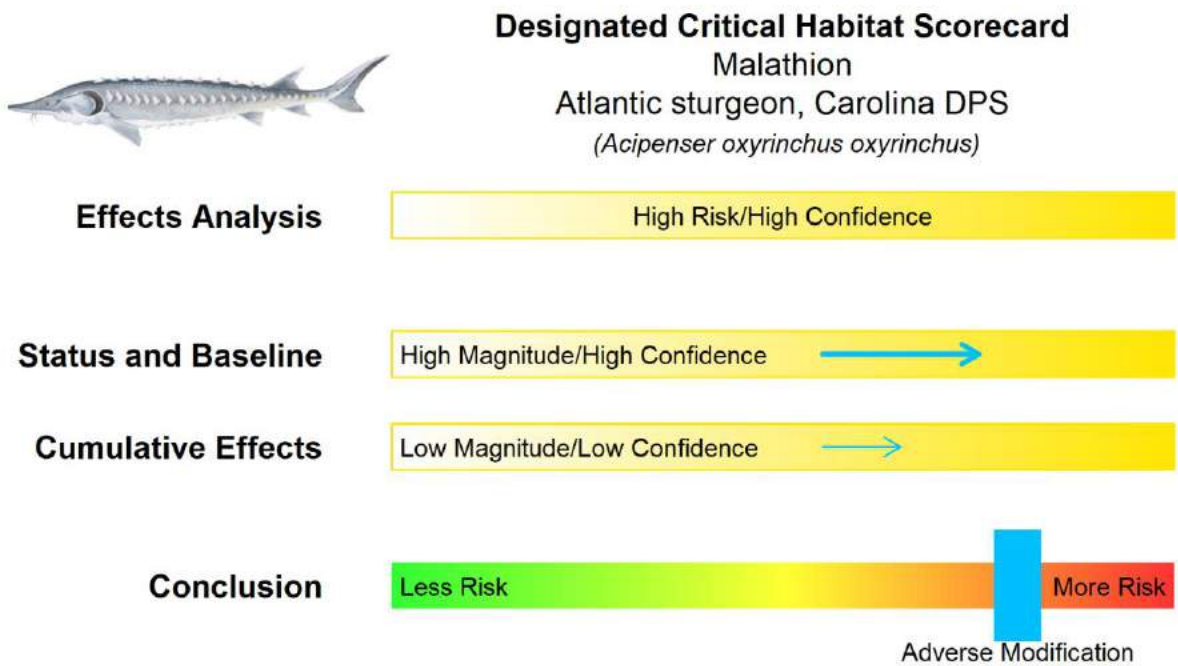

Figure 37. Designated Critical Habitat Scorecard; Atlantic sturgeon, Carolina DPS, Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Malathion may be applied anywhere in this species critical habitat for mosquito control. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

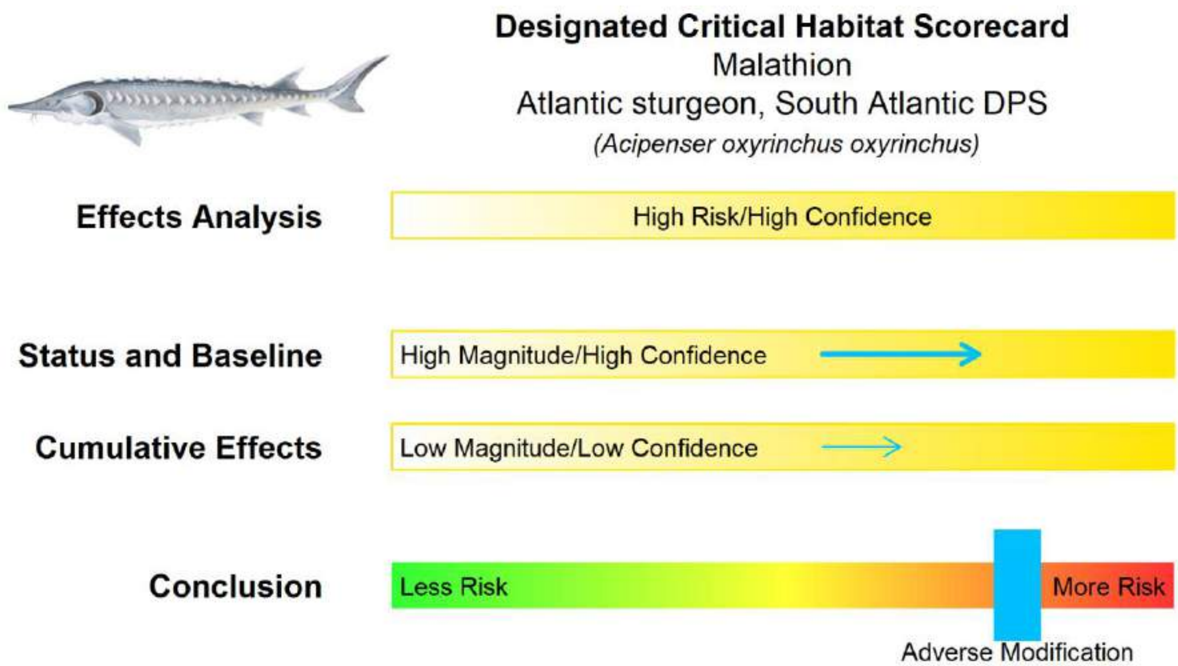

Figure 38. Designated Critical Habitat Scorecard; Atlantic sturgeon, South Atlantic DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey species and degradation of water quality are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence

- Contaminants (e.g., pesticides).
- Impassable barriers limit spawning to limited sections
- Elevated water temperatures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future elevated temperatures likely. Global climate change may threaten PBFs.
- Anticipated hydrologic changes in freshwater areas may further affect PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Malathion may be applied anywhere in this species critical habitat for mosquito control. Anticipated reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

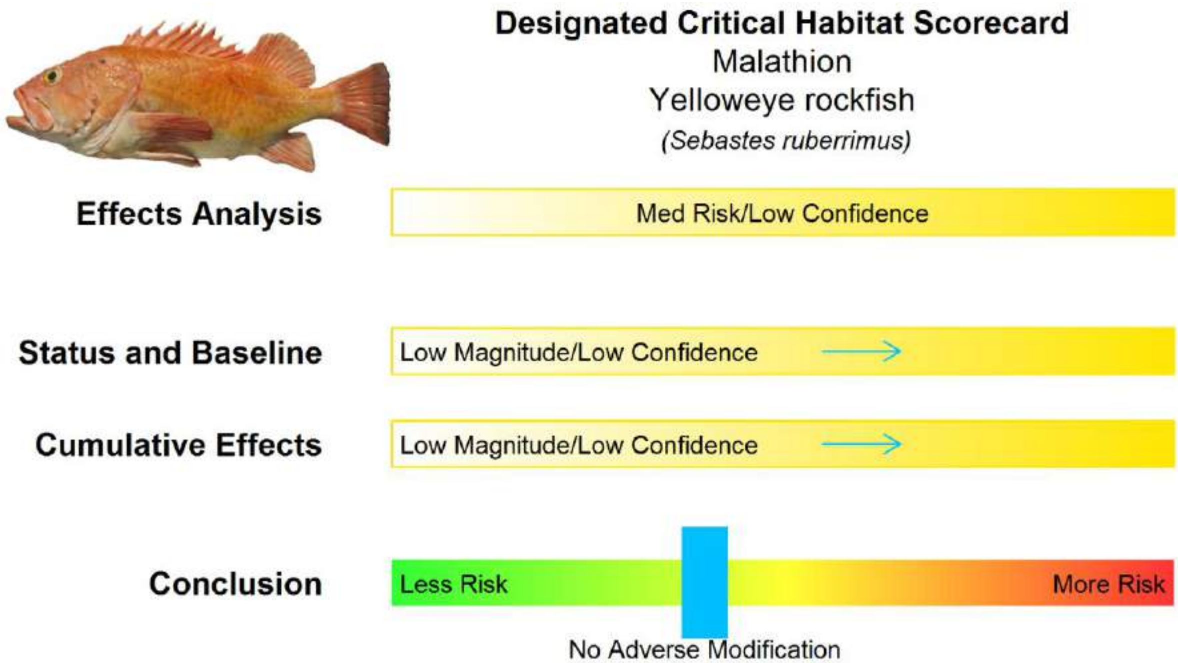

Figure 39. Designated Critical Habitat Scorecard; Yelloweye rockfish; Malathion

Effects Analysis: Medium risk/Low confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted in their marine habitats.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Adverse environmental factors have led to prey reductions and recruitment failures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.

Conclusion: We have low confidence in EECs predicted for the marine habitats. We find that the overall risk is medium and the confidence associated with that risk is low. We do not anticipate reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

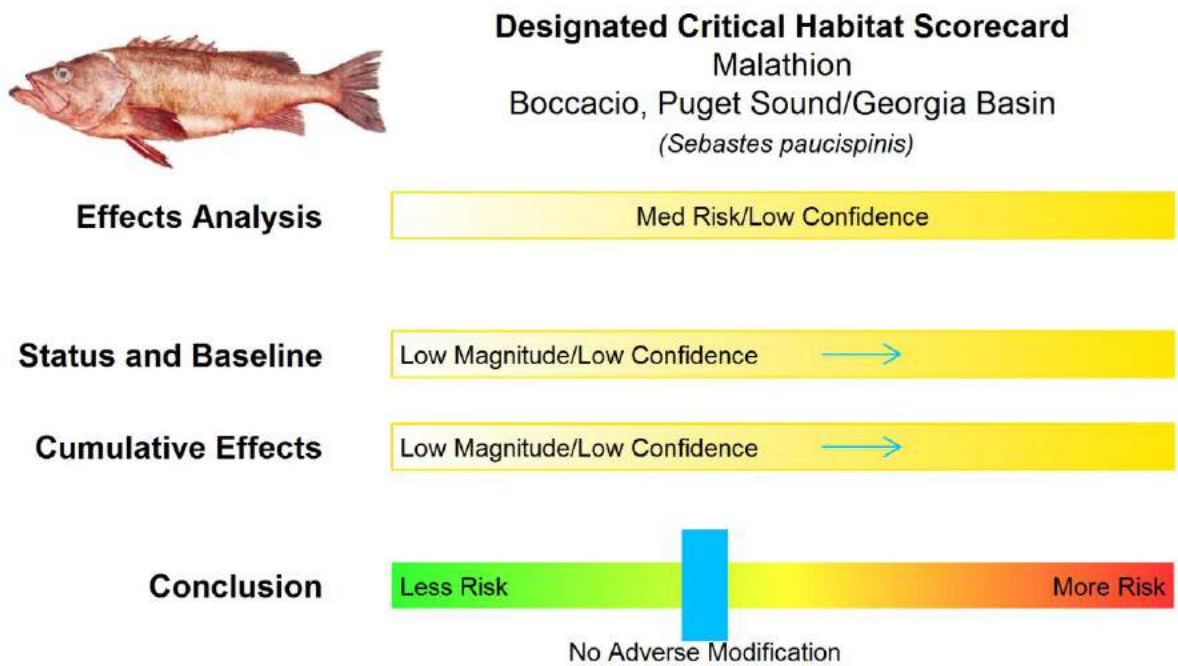

Figure 40. Designated Critical Habitat Scorecard; Boccacio, Puget Sound/Georgia Basin; Malathion

Effects Analysis: Medium risk/Low confidence

- Reductions in prey species and degradation of water quality in marine habitats are not anticipated to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted in their marine habitats.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Adverse environmental factors have led to prey reductions and recruitment failures.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.

Conclusion: We have low confidence in EECs predicted for the marine habitats. We find that the overall risk is medium and the confidence associated with that risk is low. We do not anticipate reductions in prey and degradation of water quality will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

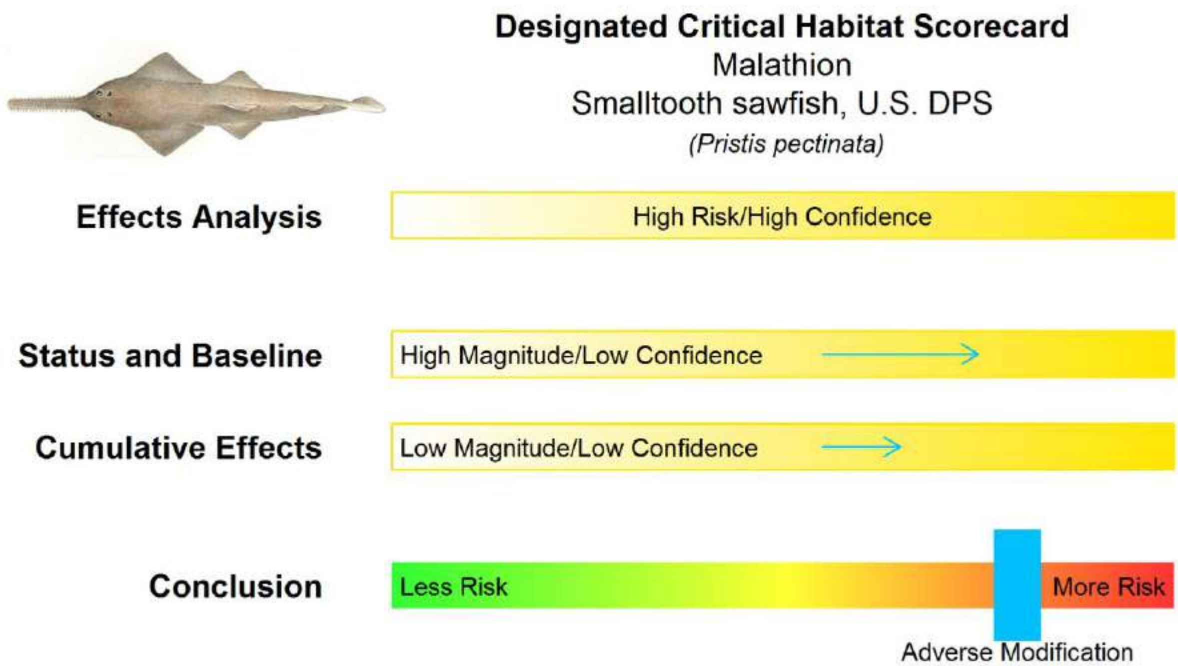

Figure 41. Designated Critical Habitat Scorecard; Smalltooth sawfish, U.S. DPS; Malathion

Effects Analysis: High risk/High confidence

- Reductions in prey species are likely to reduce the overall conservation value of designated critical habitat.
- We find high confidence of high risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/Low confidence

- Loss and degradation of female pupping sites and juvenile rearing habitats.
- Point and non-point contaminants.
- Marine Debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Future losses in vegetated shallow water habitats from developmental pressures, changes in ocean conditions, and hydrology may further threaten PBFs.

Conclusion: We find a high likelihood of exposure and effects to designated critical habitat. Critical habitat is most at risk in areas where there is extensive overlap with use sites. Malathion may be applied anywhere in this species critical habitat for mosquito control. Eight use site categories, totaling more than 249,000 acres (over 8 percent of acres) are currently present in land adjacent to designated critical habitat. Anticipated reductions in prey will reduce conservation values throughout designated critical habitat over the 15-year action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

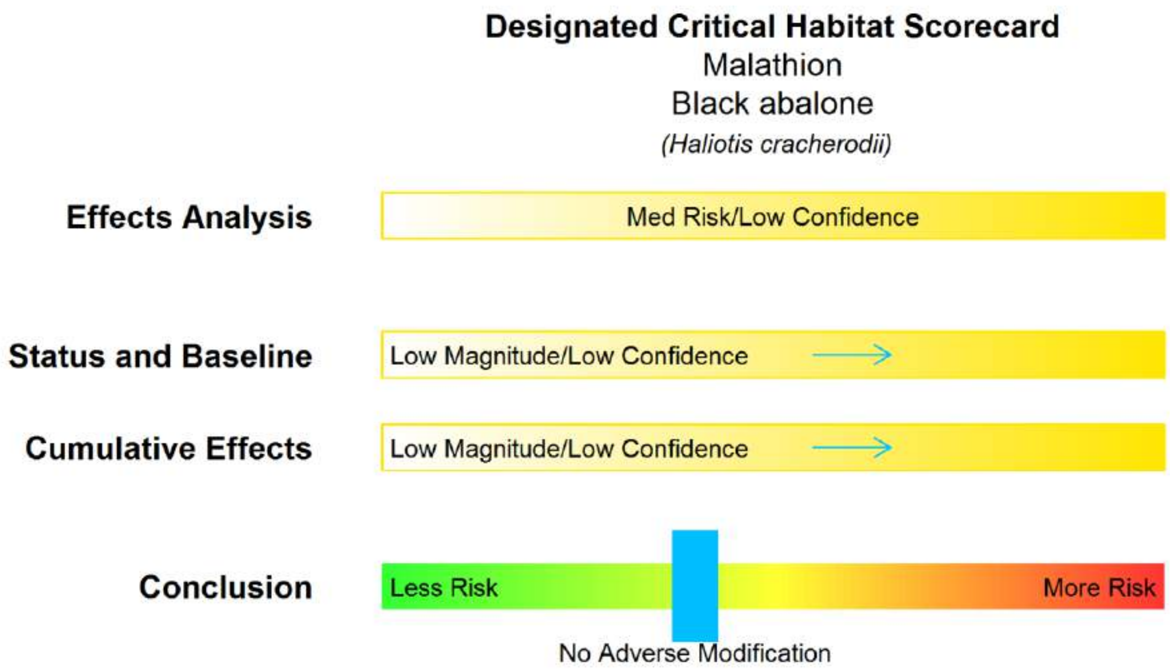

Figure 42. Designated Critical Habitat Scorecard; Black abalone; Malathion

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey species and degradation of water quality in marine nearshore and inter-tidal habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Habitat destruction.
- Disease.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Developmental pressures could reduce available habitat and create competition for space with other marine invertebrates.
- Changes in ocean conditions (ocean acidification) may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical and biological features within nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat of Black Abalone. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

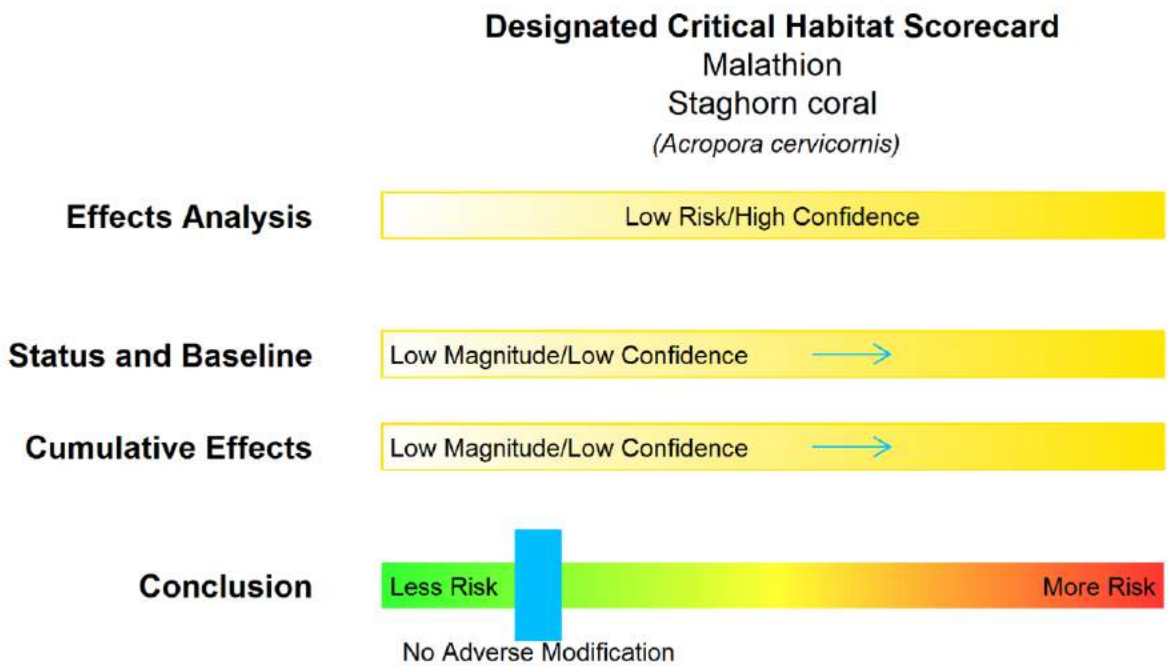

Figure 43. Designated Critical Habitat Scorecard; Staghorn coral; Malathion

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in PBFs or reductions in the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted and PBFs identified.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease (white band).
- Habitat destruction.
- Bleaching (temperature variations).
- Sedimentation.
- Algal overgrowth (nutrification).

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions (e.g. increased water temperture and acidification) may threaten PBFs.

Conclusion: There are no physical and biological features identified in Staghorn Coral designated critical habitat that could be affected by the proposed action. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

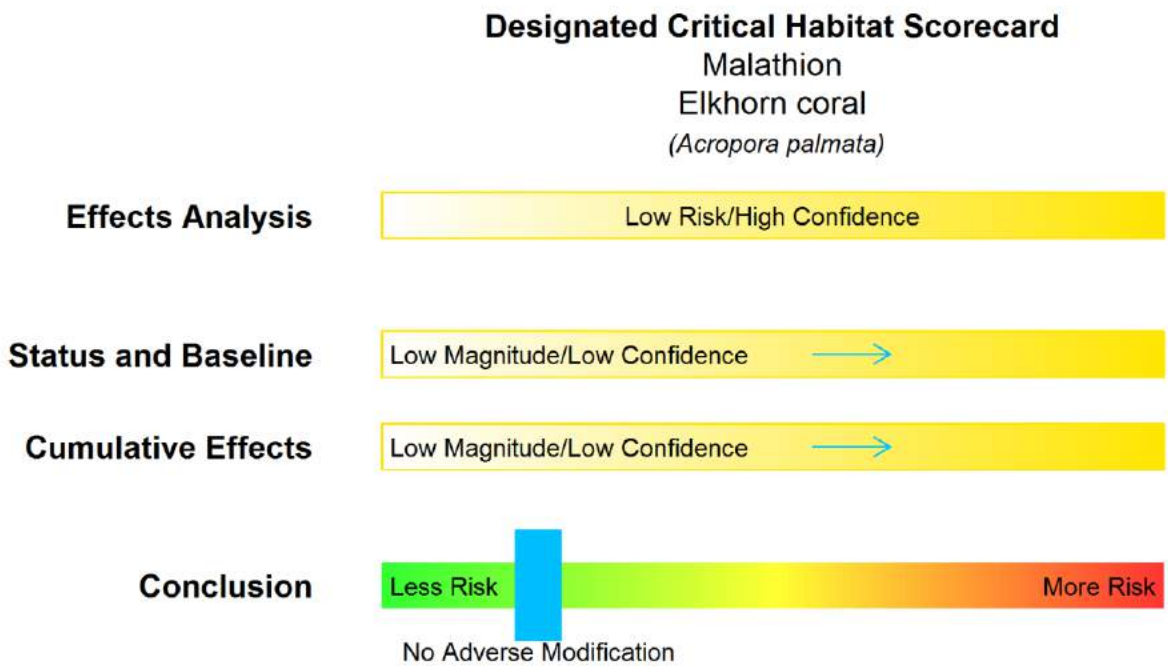

Figure 44. Designated Critical Habitat Scorecard; Elkhorn coral; Malathion

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in PBFs or reductions in the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted and PBFs identified.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease (white band).
- Habitat destruction.
- Bleaching (temperature variations).
- Sedimentation.
- Algal overgrowth (nutrification).

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions (e.g. increased water temperature and acidification) may threaten PBFs.

Conclusion: There are no physical and biological features identified in Elkhorn Coral designated critical habitat that could be affected by the proposed action. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

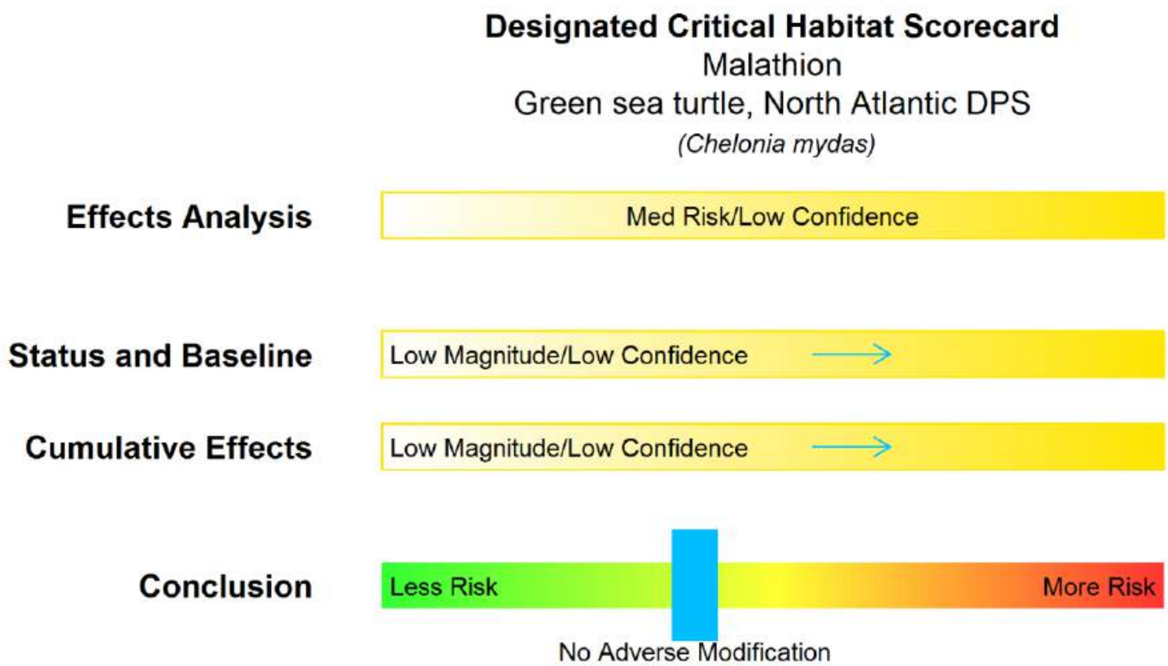

Figure 45. Designated Critical Habitat Scorecard; Green sea turtle, North Atlantic DPS; Malathion

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in water quality in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease.
- Point and non-point pollution.
- Marine debris continues to build in critical habitat.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical or biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

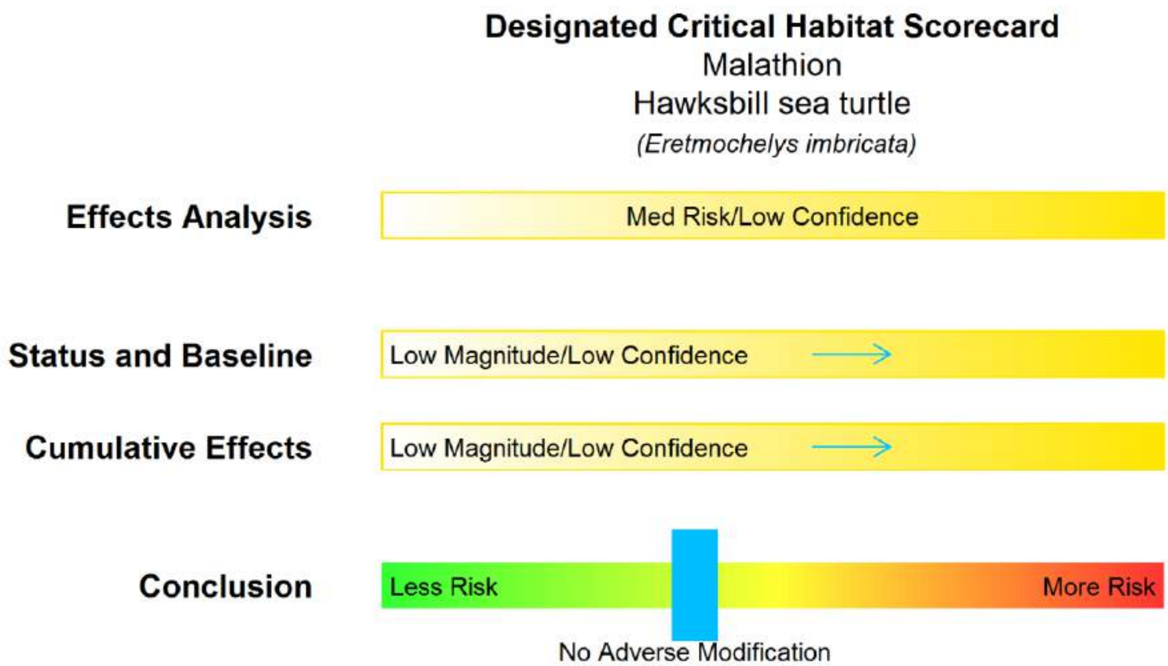

Figure 46. Designated Critical Habitat Scorecard; Hawksbill sea turtle; Malathion

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in water quality in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease.
- Point and non-point pollution.
- Marine debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical and biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

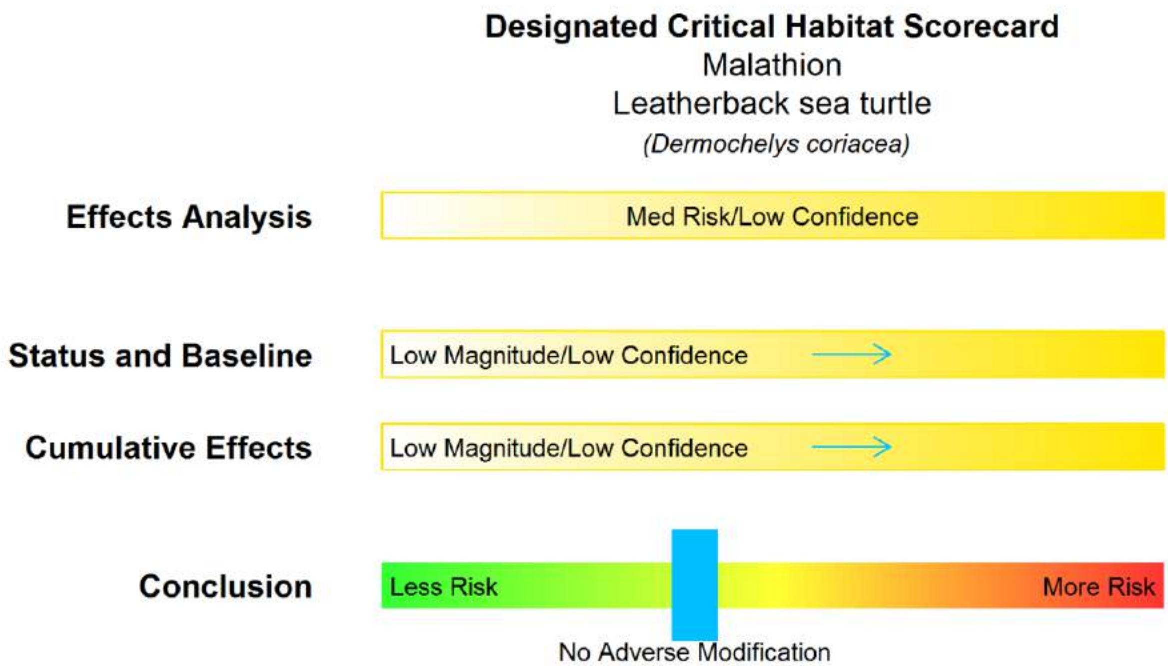

Figure 47. Designated Critical Habitat Scorecard; Leatherback sea turtle; Malathion

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Disease.
- Point and non-point pollution.
- Marine debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical and biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

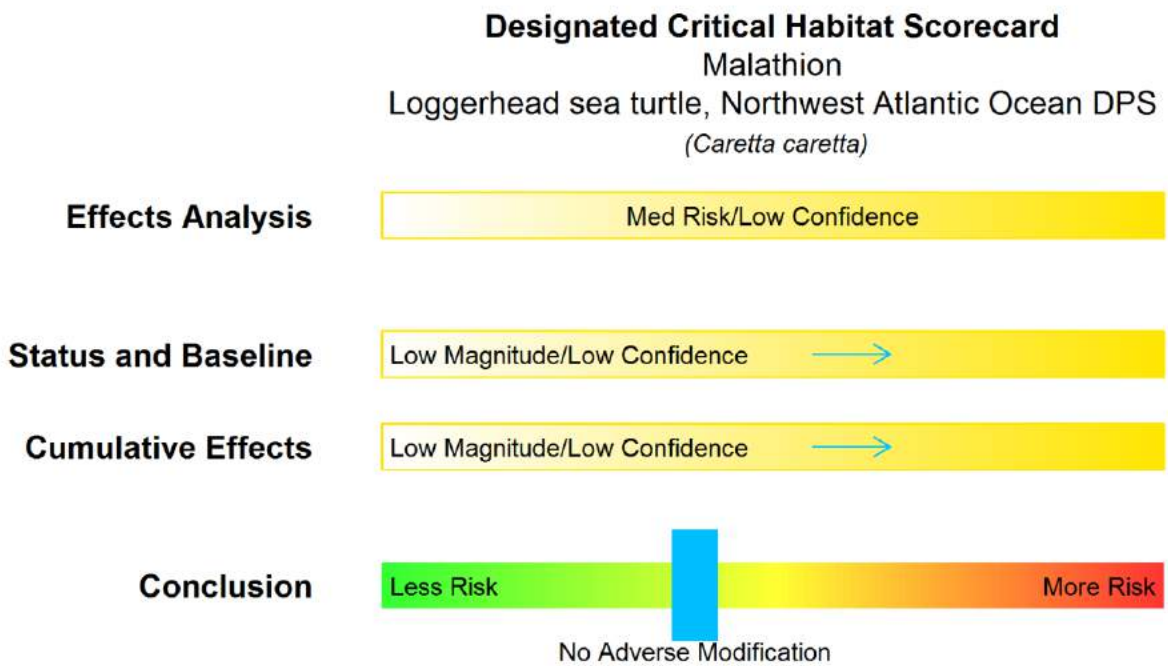

Figure 48. Designated Critical Habitat Scorecard; Loggerhead sea turtle, Northwest Atlantic Ocean DPS; Malathion

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Point and non-point pollution.
- Marine debris.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction may threaten PBFs.

Conclusion: The stressors of the action may negatively affect relevant physical and biological features within marine and nearshore habitats. However, we have low confidence in the EECs predicted for the marine nearshore habitats. We do not anticipate that the stressors of the action will reduce the overall conservation value of the designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

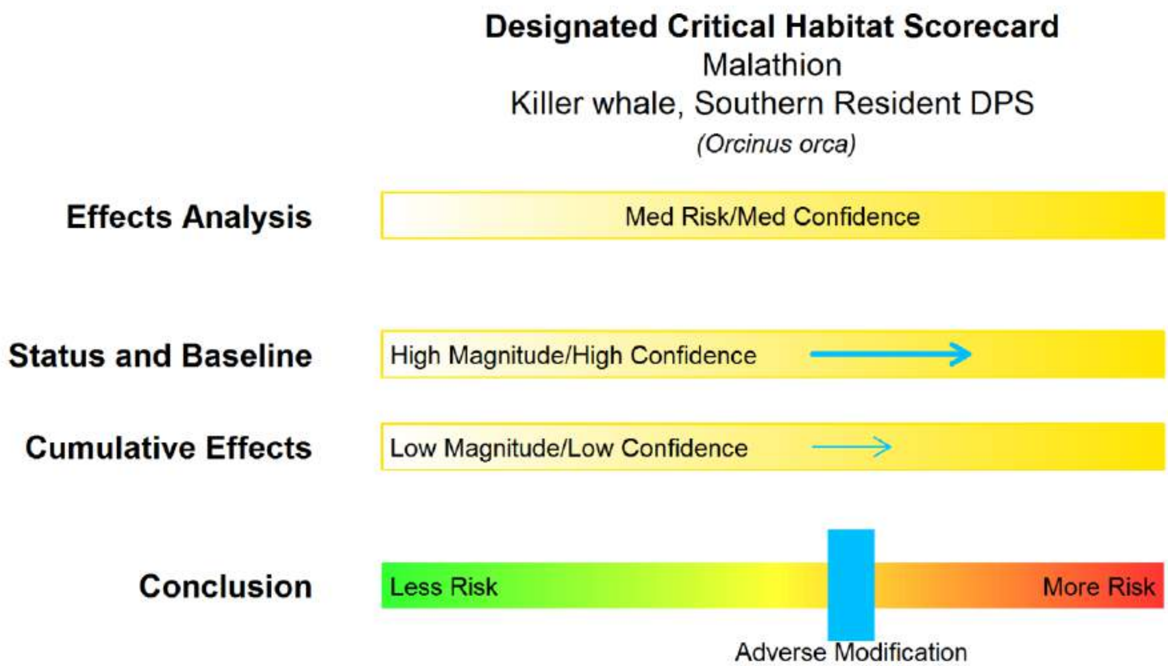

Figure 49. Designated Critical Habitat Scorecard; Killer whale, Southern Resident DPS; Malathion

Effects Analysis: Medium risk/Medium confidence
- Reductions in prey species availability (i.e. recruiting into designated critical habitat) are likely to reduce the overall conservation value of designated critical habitat.
- We find medium confidence of medium risk due to expected exposures predicted in habitats.

Status and Baseline: Increased risk; High magnitude/High confidence
- Depleted prey throughout designated critical habitat.
- Point and non-point contaminants.
- Noise disturbance.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence
- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Altered hydrology and affects to prey brought about by climate change.
- Increased stresses (e.g., temperature) to freshwater habitats critical to prey.

Conclusion: We do not anticipate stressors of the action will directly affect physical and biological features (PBFs). Reductions in suitable prey and degradation of water quality are unlikely throughout designated critical habitat of Southern Resident Killer Whale from this action. However, indirectly, prey species (Chinook salmon) will be adversely affected by exposures anticipated in their freshwater habitats. The likelihood and magnitude of toxic effects will reduce the overall conservation value of designated critical habitat by reducing the recruitment and availability of this important prey. We find that the overall risk is medium and the confidence associated with that risk is medium over the 15-year duration of the action.

Malathion is likely to adversely modify designated critical habitat: Adverse Modification

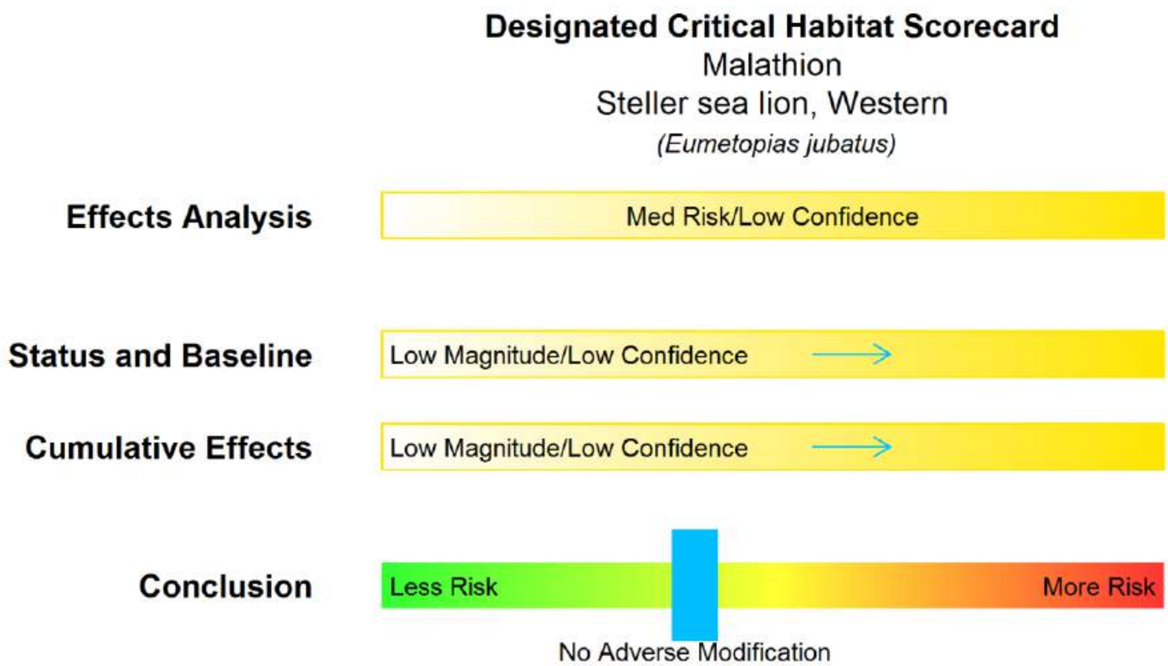

Figure 50. Designated Critical Habitat Scorecard; Steller sea lion, Western; Malathion

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Point and non-point contaminants/pollution.
- Habitat degradation.
- Oil and gas exploration.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction/activities may threaten PBFs.

Conclusion: The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of Steller Sea Lion (Western DPS). However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

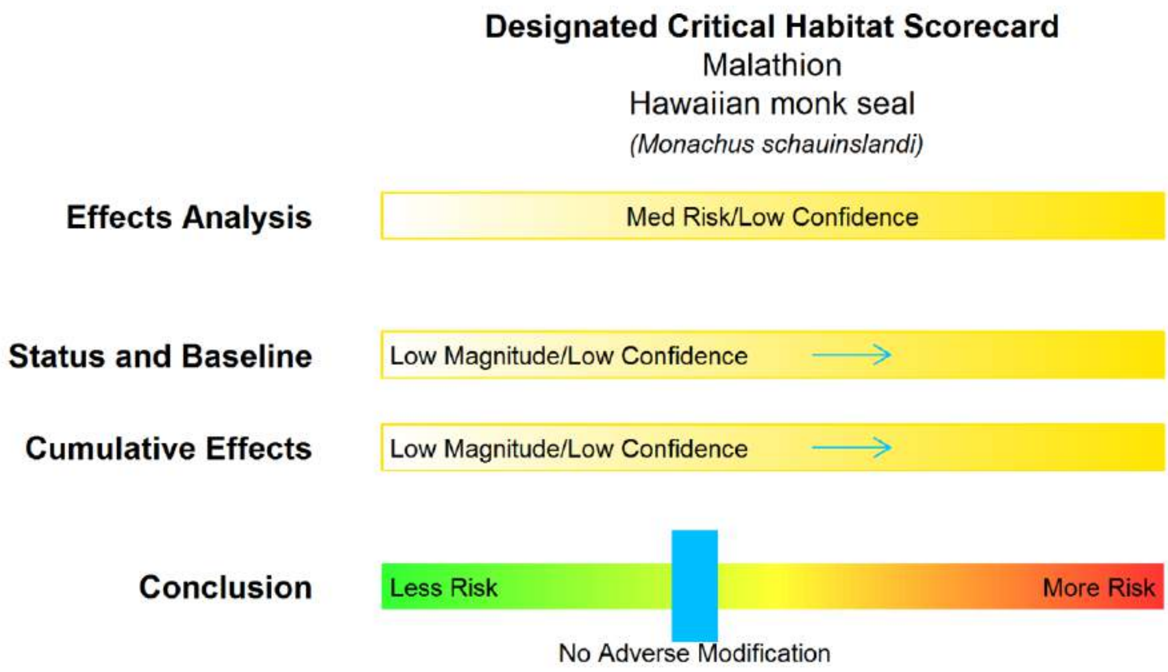

Figure 51. Designated Critical Habitat Scorecard; Hawaiian monk seal; Malathion

Effects Analysis: Medium risk/Low confidence

- We do not anticipate reductions in prey in marine and nearshore habitats to reduce the overall conservation value of designated critical habitat.
- We find low confidence of medium risk due to exposures predicted.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Limitations in food.
- Marine debris (entanglement).
- Habitat degradation.

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.
- Increased coastal construction/activities may threaten PBFs.

Conclusion: The stressors of the action may negatively affect a relevant physical and biological feature within nearshore designated critical habitat of Hawaiian Monk Seal. However, we have low confidence in the EECs predicted for the marine nearshore habitats. The likelihood and magnitude of toxic effects are not likely to reduce the overall conservation value of the marine portion of their designated critical habitat. We find that the overall risk is medium and the confidence associated with that risk is low over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

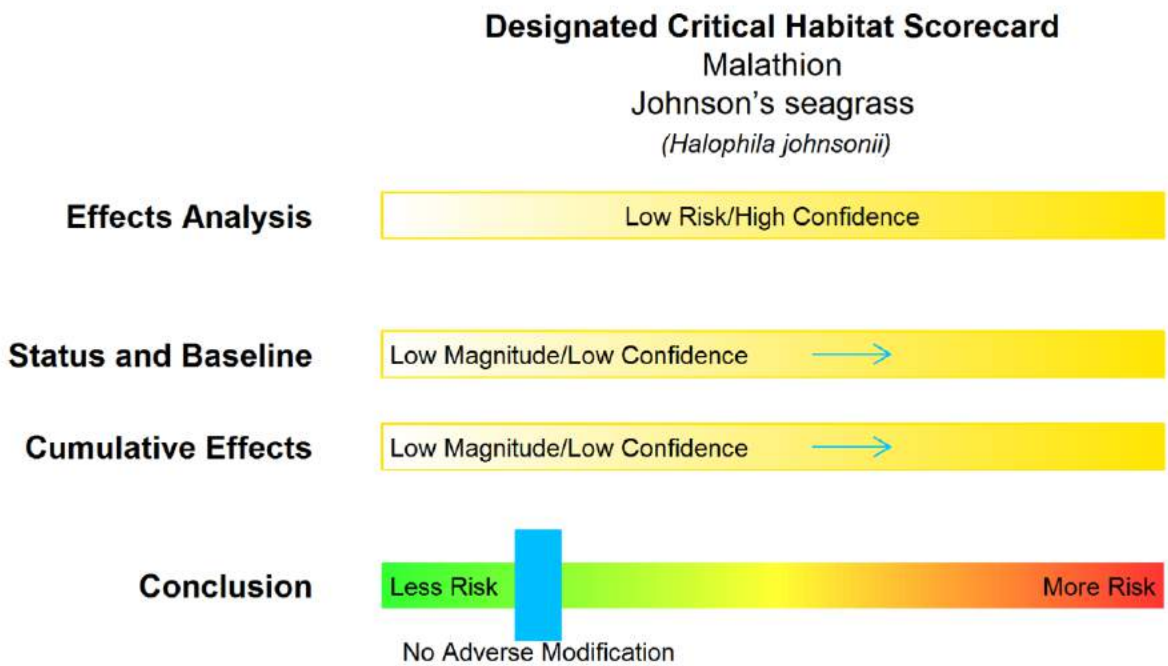

Figure 52. Designated Critical Habitat Scorecard; Johnson's seagrass; Malathion

Effects Analysis: Low risk/High confidence

- We do not anticipate reductions in PBFs or reductions in the overall conservation value of designated critical habitat.
- We find high confidence of low risk due to exposures predicted and PBFs identified.

Status and Baseline: Minimal increase in risk; Low magnitude/Low confidence

- Degraded water quality.
- Habitat destruction
- Siltation due to land-use practices.
- Algal overgrowth (nutrification).

Cumulative Effects: Minimal increase in risk; Low magnitude/Low confidence

- Changes in ocean conditions brought about by climate change may threaten PBFs.

Conclusion: Water quality is a physical and biological features identified in Johnson's seagrass designated critical habitat. However, we do not anticipate exposures from the stressors of the action to be sufficient to reduce conservation values of this PBF. We find that the overall risk is low and the confidence associated with that risk is high over the 15-year duration of the action.

Malathion is not likely to adversely modify designated critical habitat: No Adverse Modification

CHAPTER 25

CONCLUSION

TABLE OF CONTENTS

LIST OF TABLES

25 Conclusion

25.1 Chlorpyrifos

After reviewing the current status of the Endangered Species Act (ESA)-listed species, the environmental baseline within the action area, the effects of the proposed action, any effects of interrelated and interdependent actions, and cumulative effects, it is the National Marine Fisheries Services'(NMFS') biological opinion that the Environmental Protection Agency's (EPA's) registration of the uses, as described by product labels, of all pesticide products containing chlorpyrifos (the Action) is likely to jeopardize the continued existence of thirty-eight species and to destroy or adversely modify the designated critical habitat of thirty-seven listed species (***Table 1,Table 2***).

25.2 Diazinon

After reviewing the current status of the ESA-listed species, the environmental baseline within the action area, the effects of the proposed action, any effects of interrelated and interdependent actions, and cumulative effects, it is NMFS' biological opinion that the EPA's registration of the uses, as described by product labels, of all pesticide products containing diazinon (the Action) is likely to jeopardize the continued existence of twenty-five listed species and to destroy or adversely modify the designated critical habitat of eighteen listed species (***Table 1, Table 2***).

25.3 Malathion

After reviewing the current status of the ESA-listed species, the environmental baseline within the action area, the effects of the proposed action, any effects of interrelated and interdependent actions, and cumulative effects, it is NMFS' biological opinion that the EPA's registration of the uses, as described by product labels, of all pesticide products containing malathion (the Action) is likely to jeopardize the continued existence of thirty-eight listed species and to destroy or adversely modify the designated critical habitat of thirty-seven species (***Table 1, Table 2***).

Page

26 Reasonable and Prudent Alternatives & Reasonable and Prudent Measures

26.1 RPA Introduction

When the National Marine Fisheries Service (NMFS) concludes that an action is likely to jeopardize an Endangered Species Act (ESA)-listed species or destroy or adversely modify critical habitat, NMFS suggests a reasonable and prudent alternative (RPA) that would allow the action to proceed in compliance with section 7(a)(2) and that can be taken by the action agency and the applicant (ESA Section 7(a)(3)(A)). Joint NMFS and U.S. Fish and Wildlife Service regulations (50 CFR §402.02) implementing section 7 define "jeopardize the continued existence of" means "to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a ESA-listed species in the wild by reducing the reproduction, numbers, or distribution of that species" (50 CFR §402.02). As noted above, NMFS relies on statutory language to determine adverse modification.

The NMFS' implementing regulations define reasonable and prudent alternatives as alternative actions, identified during formal consultation, that: (1) can be implemented in a manner consistent with the intended purpose of the action; (2) can be implemented consistent with the scope of the action agency's legal authority and jurisdiction; (3) are economically and technologically feasible; and (4) NMFS believes would avoid the likelihood of jeopardizing the continued existence of ESA-listed species or resulting in the destruction or adverse modification of critical habitat (50 CFR §402.02). The overarching requirement is that an RPA must be capable of avoiding jeopardizing ESA-listed species and adversely modifying critical habitat – all other elements of the definition must be evaluated within this context (*Greenpeace v. NMFS*, 55 F. Supp. 2d 1248, 1268 (W.D. Wa. 1999)). NMFS in the preamble to the final section 7 regulations make clear that the overriding consideration is whether a RPA avoids the likelihood of jeopardy. NMFS notes that the action agency's responsibility "permeates the full range of discretionary authority held by the action agency." Thus, NMFS can specify an RPA that involves the maximum exercise of the action agency's authority when the Services deem necessary to avoid the likelihood of jeopardy (51 FR 19926, 19937 (June 3, 1986)).

The other three factors are intended to implement the statutory phrase "can be taken." The third factor, technological and economic feasibility, refers to the ability of the federal agency to implement the RPA: "[t]he requirement that a RPA be 'economically and technologically feasible' only requires that the Corps have the resources and technology necessary to implement the RPA." *In Re: Operation of the Missouri River System Litigation.* 363 F. Supp. 2d 1145, 1161 (D. Minn. 2004), citing *Kandra v. U.S.*, 145 F.Supp. 2d 1192, 1207 (D. Ore.) ("the RPAs must be economically and technically feasible for *the government* to implement."); see also San Luis & Delta-Mendota Water Authority v. Jewell, 2014 WL 975130 at 38-40 (C.A.9 (Cal.)). This regulatory factor was included in the final section 7 implementing regulations in response to a comment, without further explanation or discussion. The ESA contains no requirement for analysis of economic impacts resulting from implementation of a RPA, and the insertion of the phrase "economically feasible" in regulation cannot create this requirement. Any obligation that NMFS "balance the benefit to the species against the economic and technical burden on the industry before approving an RPA would be fundamentally inconsistent with the purposes of the

ESA and with case law interpreting the Act." *Greenpeace v. NMFS,* 55 F. Supp. 2d 1248, 1267 (W.D. Wash. 1999). While the Services will defer in most cases to the action agency's expertise as to whether a RPA is reasonable, including whether the RPA is technologically and economically feasible, the Services cannot abdicate their duty to formulate and recommend RPAs (51 FR at 19952). However, the action agency may choose or may be obligated to conduct an economic analysis and to evaluate impacts to interests other than the applicants when it implements a RPA pursuant to its authorities.

In this Opinion, NMFS concluded that the Environmental Protection Agency's (EPA's) proposed registration of chlorpyrifos, diazinon and malathion is likely to jeopardize 38 listed species and likely to adversely modify or destroy the designated critical habitat of 37 species. NMFS reached these conclusions because predicted concentrations of these three a.i.s are likely to have direct and indirect adverse effects to these species and to the primary biological features of their designated critical habitat. As a result, affected species are likely to suffer reductions in viability from one or more of the a.i.s given the severity of expected changes in abundance and productivity associated with the proposed action. These adverse effects are expected to appreciably reduce the likelihood of both the survival and recovery of these listed species and reduce the conservation value of some of the species' designated critical habitat.

The RPA accounts for the following issues: (1) the action will result in exposure to other chemical stressors in addition to the a.i. that may increase the risk of the action to ESA-listed species, including unspecified inert ingredients, adjuvants, and tank mixes; (2) exposure to chemical mixtures containing the a.i.s and other chemical compounds may result in greater toxicity; and (3) exposure to other chemicals and physical stressors (*e.g.,* temperature) in the baseline habitat will likely intensify response to the a.i.s.

The action as implemented under the RPA will remove the likelihood of jeopardy and of destruction or adverse modification of critical habitat by reducing exposure of the stressors of the action. In the proposed RPA, NMFS does not attempt to ensure there is no take of ESA-listed species. NMFS concludes that take will likely occur, and has provided an incidental take statement exempting that take from the take prohibitions as long as the action is conducted in compliance with the terms and conditions of the incidental take statement. Avoiding take altogether would most likely entail canceling registration, or prohibiting all use in watersheds inhabited by listed species. The goal of the RPA is to reduce exposure to ensure that the action is not likely to jeopardize ESA-listed species or destroy or adversely modify critical habitat.

For each active ingredient, the elements of the RPA apply only to the range of the ESUs/DPSs where NMFS has determined that EPA cannot ensure that its registration of that a.i. avoids jeopardy or the destruction or adverse modification of critical habitat (Chapter 25). These elements rely upon recognized practices for reducing loading of pesticide products into aquatic habitats.

Overall, the RPA listed here focus on reducing exposure potential to listed species and their habitats by targeting risk reduction measures that effectively reduce drift and runoff. The RPA include pesticide use restrictions that shall be specified on Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) labels of all pesticide products containing the three active ingredients; this shall be accomplished by incorporating the required elements of the RPA into the "Directions for Use" section of the FIFRA labels or on EPA Endangered Species Protection

Program Bulletins that serve as enforceable extensions to these labels (https://www.epa.gov/endangered-species/endangered-species-protection-bulletins).

The RPA listed here also incorporates risk reduction measures for pesticide users that participate in conservation activities. These include: 1) installing/maintaining riparian systems alongside aquatic habitats, and 2) participation in a recognized pesticide stewardship plan. Pesticide users that take advantage of these activities receive full points for required risk reduction measures for drift and runoff/drainage.

Riparian areas occur alongside watercourses or water bodies and are typically distinct from surrounding lands due to their unique soil and vegetation characteristics that are influenced by the hydrologic conditions of the soil. Pesticides can move from treated agricultural and forested areas via spray drift and surface water runoff into the broader environment. Riparian areas filter runoff and intercept drift thereby reducing loading into off target water bodies. Generally, the use of riparian areas, coupled with low-drift application methods, substantially reduce drift deposition and runoff into sensitive aquatic habitats adjacent to pesticide use sites. Therefore, a functional riparian zone substantially reduces pesticide loading, potentially negating the need for no-spray buffers. The effectiveness in reducing pesticide loading depends on site-specific factors such as dimensions, type, and complexity of the riparian vegetation.

Pesticide stewardship plans[1], such as Salmon-Safe, work with landowners to create a management plan that reduces or eliminates use of pesticides thereby removing potential exposure to listed species and their habitats. Therefore, landowners that participate in such plans would receive full credit for required risk reduction measures.

26.1.1 Reasonable and Prudent Alternatives

Five distinct elements are required to ensure jeopardy is avoided and to ensure designated critical habitat is not destroyed or modified. These elements are:

1. Reduce pesticide loading for high risk use sites;
2. Limit the frequency of application to once per year for persistent pesticides i.e., chlorpyrifos;
3. Limit area of application for mosquito control;
4. Limit area of application for wide area use;
5. Employ an effectiveness monitoring plan.

Element 1 involves three options which EPA can implement through label revisions that would reduce pesticide loading in listed species aquatic habitats (Table 1). The first of these options changes the action by prohibiting the use of high risk uses within a species range and/or modifying labels based on actual usage. In the second option, EPA could require specific no application buffers and mandate a 6 meter vegetative filter strip for all high risk uses within the species range. The third option provides flexibility for pesticide users to select risk reduction measures using the point system approach described below. This option includes a variety of risk reduction measures including no-spray buffers, vegetative filter strips, spray drift reduction technologies, and participation in pesticide stewardship programs such as "Salmon-Safe".

---

[1] NMFS approval of stewardship plan required to receive risk reduction credit

Table 1. RPA Elements

RPA Element	Description
Element 1	Reduce pesticide loading for all high risk use sites. Choose 1(a) or 1(b) or 1(c). 1(a) Remove label authorization for all high risk uses. If current usage on use sites effectively reduces exposure[2], modify labels to reflect current usage. 1(b) Modify labels to include standard buffers and vegetative filter strips: 300 meter no-spray buffer for all aerial applications; 150 meter buffer for all ground applications; 6 meter vegetative filter strip for all applications. 1(c) Point System. Implement a combination of risk reduction measures to reduce pesticide drift, runoff, and drainage.
Element 2	Limit the frequency of application to once per year for persistent pesticides e.g. chlorpyrifos.
Element 3	Restrict mosquito applications to residential and developed areas within species' range.
Element 4	Restrict wide area use to residential and developed areas with spot treatment only.
Element 5	EPA shall, in close coordination with NMFS Office of Protected Resources, develop and implement an effectiveness monitoring plan to ensure the RPA(s) selected is/are feasible, effective, and implemented.

26.1.2 Points System Overview: Element 1(c)

Pesticide end-users could also follow a simple point system to arrive at sufficient risk reduction measures. The points system is based on the European Union's Mitigating the Risks of Plant Protection Products in the Environment, referred to as MAgPIE (Alix et al. 2017). While the goal of MAgPIE was to develop a harmonized approach for risk management among EU countries, the approach achieves quantifiable reductions in pesticide loading while allowing maximum flexibility for the grower/applicator. It also rewards landowners who are already implementing reduction measures such as Best Management Practices (BMPs) that reduce loading and improve habitat for listed species.

Important aspects of the points approach:

- The pesticide applicator can choose from a list of risk reduction measures (e.g. Table 2) listed on EPA's Bulletins Live website.
- Each risk reduction measure on the list has a point value based on its effectiveness at reducing loading from drift and runoff/drainage.

[2]Requires NMFS concurrence that EPA-proposed alternative based on usage information effectively reduces exposure

- The applicator can choose which risk reduction measures to implement as long as the required number of points are achieved for each exposure pathway (drift and runoff/drainage).
- The point system is only required for high risk uses. High risk uses are those which received a high rating for effect of exposure and a high or medium rating for likelihood of exposure as presented in the Effects of the Proposed Action.

Risk reduction measures and associated points are presented below in Table 2, Table 3, and Table 4. The RPA and RPM for each of the three pesticides apply to applications on high risk use sites within 300 meters adjacent to, or that drain to listed species aquatic habitats for which jeopardy or adverse modification of designated critical habitat was determined.

Table 2. Chlorpyrifos Risk Reduction Measures and Associated Points

Drift Measures	Estimated % reduction in loading	Points	Runoff/drainage Measures	Estimated % reduction in loading	Points
No Spray Drift Buffers :			No Spray Buffer ≥300 meters to listed species habitat or water that drains to habitat	99	80
Ground boom[1] /chemigation buffer:

26.2 Reasonable and Prudent Alternatives for Each Species and Pesticide

This section describes chemical-specific RPA elements for each of the ESA-listed species for which jeopardy or adverse modification of designated critical habitats was determined.

26.2.1 Chlorpyrifos RPA

- Reduce pesticide loading for all high risk use sites.
    - 1(a) Remove label authorization for all high risk uses. If current usage on use sites effectively reduces exposure, modify labels to reflect current usage.
    - 1(b) Modify labels to include 300 meter no-spray buffer for all aerial applications; 150 meter buffer for all ground applications; 6 meter vegetative filter strip for all applications.
    - 1(c) Point System. Implement a combination of risk reduction measures to reduce pesticide drift and runoff (Table 5).
- Limit the frequency of application to once per year.
- Restrict mosquito applications to residential and developed areas within species' range.
- Restrict wide area use to residential and developed areas with spot treatment only.
- EPA shall, in close coordination with NMFS Office of Protected Resources, develop and implement an effectiveness monitoring plan to ensure the elements selected are feasible, effective, and implemented.

Table 5. High risk uses for chlorpyrifos and risk reduction points required for drift and runoff/drainage

Chlorpyrifos	**Risk Reduction Options for High Risk Uses**		
Species	**Remove label authorization for all high risk uses**	**No-spray Buffer: 300m aerial application, 150m ground application; and 6m vegetative filter strip**	**Required Points: Drift Runoff/drainage**
Chum salmon , Columbia River Evolutionarily Significant Unit (ESU) (T)	Right of Way Pasture Developed	Right of Way Pasture Developed	80 drift 80 runoff

Killer whale, Southern Resident DPS	Implementation of RPAs for all west coast Chinook ESUs		

For smalltooth sawfish, risk reduction measures are only required at use sites within the species nursery areas, as opposed to within the entire species range.

26.2.2 Diazinon RPA

- Reduce pesticide loading for all high risk use sites.
  - 1(a) Remove label authorization for all high risk uses. If current usage on use sites effectively reduces exposure, modify labels to reflect current usage.
  - 1(b) Modify labels to include 300 meter no-spray buffer for all aerial applications; 150 meter buffer for all ground applications; 6 meter vegetative filter strip for all applications.
  - 1(c) Point System. Implement a combination of risk reduction measures to reduce pesticide drift and runoff (Table 6)
- EPA shall, in close coordination with NMFS Office of Protected Resources, develop and implement an effectiveness monitoring plan to ensure the RPA(s) selected is/are feasible, effective, and implemented.

Table 6. High risk uses for diazinon and risk reduction points required for drift and runoff

Diazinon	**Risk Reduction Options for High Risk Uses**		
Species	**Remove label authorization for all high risk uses**	**No-spray Buffer: 300m aerial application, 150m ground application; and 6m vegetative filter strip**	**Required Points: Drift Runoff/drainage**
Chinook salmon, Central Valley spring-run ESU (T)	Orchards and Vineyards Vegetables and Ground Fruit	Orchards and Vineyards Vegetables and Ground Fruit	80 drift 80 runoff

26.2.3 Malathion RPA

- Reduce pesticide loading for all high risk use sites.
    - 1(a) Remove label authorization for all high risk uses. If current usage on use sites effectively reduces exposure, modify labels to reflect current usage.
    - 1(b) Modify labels to include 300 meter no-spray buffer for all aerial applications; 150 meter buffer for all ground applications; 6 meter vegetative filter strip for all applications.
    - 1(c) Point System. Implement a combination of risk reduction measures to reduce pesticide drift and runoff (Table 7).
- Restrict mosquito applications to residential and developed areas within species' range.
- EPA shall, in close coordination with NMFS Office of Protected Resources, develop and implement an effectiveness monitoring plan to ensure the RPA(s) selected is/are feasible, effective, and implemented.

Table 7. High risk uses for malathion and risk reduction points required for drift and runoff

Malathion	**Risk Reduction Options for High Risk Uses**

26.3 RPM Introduction

Section 7(b)(4) of the ESA requires that when a proposed agency action is found to be consistent with section 7(a)(2) of the ESA, either as proposed by the action agency or modified by a RPA, and the proposed action may incidentally take individuals of ESA-listed species, NMFS will issue a statement that specifies the impact of any incidental taking of endangered or threatened species ("incidental take statement" or "ITS"). To minimize such impacts, NMFS provides reasonable and prudent measures "RPM", and terms and conditions to implement the RPM. Action agency compliance with the terms and conditions provides an exemption from the prohibitions against "take" of listed species. NMFS believes the RPM and the implementing terms and conditions described below are necessary and appropriate to minimize the impacts of incidental take on threatened and endangered species. The measures described below are nondiscretionary, and must be undertaken by the U.S. Environmental Protection Agency so that they become binding conditions for the exemption in section 7(o)(2) to apply. Section 7(b)(4) of the ESA requires that when a proposed agency action is found to be consistent with section 7(a)(2) of the ESA and the proposed action may incidentally take individuals of ESA-listed species, NMFS will issue a statement that specifies the impact of any incidental taking of endangered or threatened species. To minimize such impacts, reasonable and prudent measures, and term and conditions to implement the measures, must be provided. Only incidental take resulting from the agency actions and any specified reasonable and prudent measures and terms and conditions identified in the incidental take statement are exempt from the taking prohibition of section 9(a), pursuant to section 7(o) of the ESA.

Reasonable and prudent measures (RPM)

“Reasonable and prudent measures” are nondiscretionary measures to minimize the amount or extent of incidental take (50 C.F.R. §402.02). The reasonable and prudent measures described below are necessary and appropriate to minimize the impacts of incidental take on threatened and endangered species:

- RPM 1. Revise all chlorpyrifos, diazinon, and malathion product labels and develop relevant EPA Endangered Species Protection Plan Bulletins to conserve listed species.
- RPM 2. Develop user education program, and incident tracking and reporting system.

26.4 Incidental Take Statement

Section 9(a)(1) of the ESA prohibits the taking of endangered species without a specific permit or exemption. Protective regulations adopted pursuant to section 4(d) of the ESA extend the prohibition to threatened species. Take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct (50 CFR 222.102). Harm is further defined by NMFS an act which actually kills or injures fish or wildlife, and may to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including breeding, spawning, rearing, migrating, feeding, or sheltering (50 CFR 222.102). Incidental take is defined as takings that result from, but are is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity conducted by the Federal agency or applicant (50 CFR 402.02). Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action, whether implemented as proposed or as modified by reasonable and prudent alternatives, is not considered to be prohibited taking under the ESA provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement. NMFS cannot issue an Incidental Take Statement to cover any take of marine mammals that would also be prohibited under the Marine Mammal Protection Act, unless such take has been authorized pursuant to section 101(a)(5) of that Act. Consequently, any exemption of incidental take of marine mammals under this Incidental Take Statement is conditional upon the issuance of an authorization for such take under the MMPA.

26.4.1 Amount or Extent & Effects of Take

Section 7 regulations require NMFS to specify the impact of any incidental take of endangered or threatened species; that is, the amount or extent, of such incidental taking on the species (50 C.F.R. §402.14(i)(1)(i)). The amount of take represents the number of individuals that are expected to be taken by actions. As described earlier in this Opinion, the proposed action for this consultation is EPA’s registrations of all pesticides containing chlorpyrifos, diazinon and malathion for use as described on product labels. The proposed action includes (1) approved product labels containing chlorpyrifos, diazinon and malathion, (2) degradates and metabolites of chlorpyrifos, diazinon and malathion, (3) formulations, including other ingredients within formulations, (4) adjuvants, and (5) tank mixtures. EPA is required to reassess currently registered pesticide active ingredients every 15 years. The EPA authorizes use of these pesticide products for pest control purposes across multiple landscapes. The goal of this Opinion is to evaluate the impacts to NMFS’ listed resources from the EPA’s broad authorization of applied pesticide products.

For this Opinion, NMFS anticipates the general direct and indirect effects that would occur from EPA's registration of pesticide products to 77 listed species under NMFS' jurisdiction during the 15-year duration of the proposed action. The RPA are designed to reduce exposure but not eliminate it. Pesticide runoff and drift of chlorpyrifos, diazinon, and malathion are most likely to reach streams and other aquatic sites when they are applied to crops and other land use settings located adjacent to wetlands, riparian areas, ditches, flood plain habitats, intermittent streams, nearshore estuarine and marine habitats. These inputs into aquatic habitats are especially high when rainfall immediately follows applications, or if wind conditions exacerbate inputs from drift. The effects of pesticides and other contaminants found in urban runoff, especially from areas with a high degree of impervious surfaces, may also exacerbate degraded water quality conditions of receiving waters. Urban runoff is also generally warmer in temperature, and elevated water temperature poses negative effects to many listed species. The range of effects of the 3 a.i.s on listed species includes killing species directly and reductions in prey leading to starvation and impaired growth. For example, impaired growth lends juveniles prone to becoming prey to predators, and starvation may make species more susceptible to disease. In addition, exposed individuals may change normal behaviors (e.g. feeding, sheltering, breeding, etc.). These results are not the purpose of the proposed action. Therefore, incidental take of listed species is reasonably certain to occur over the 15-year duration of the proposed action.

Given the variability of real-life conditions, the broad nature and scope of the proposed action, and the wide-ranging distributions of individuals of listed species, the best scientific and commercial data available are not sufficient to enable NMFS to estimate a specific amount of incidental take associated with the proposed action. As explained in the Description of the Proposed Action and the Effects of the Proposed Action sections, NMFS identified multiple uncertainties associated with the proposed action. Areas of uncertainty include:

1. Limited use and exposure data on stressors of the action for non-agricultural uses of these pesticides;
2. Minimal information on exposure and toxicity for pesticide formulations, adjuvants, and other/inert ingredients within registered formulations;
3. Minimal information on tank mixtures and associated exposure estimates;
4. Limited data on toxicity of environmental mixtures;
5. Variability in annual land use, crop cover, and pest pressure;
6. Temporal and spatial variability of individuals;
7. Pesticide concentrations in nearshore estuarine and marine habitats
8. Pesticide concentrations resulting from non-agricultural uses

Additionally, NMFS recognizes there are multiple impediments that reduce the likelihood of detecting take to listed species from the use of pesticides. It's important to place the significance of mortality incidents in the proper context. Vyas (1999) concluded that most wildlife mortality is unaccounted for as only a small fraction are likely observed, reported, and confirmed. The likelihood of detecting impacts becomes even more difficult in species with limited abundance. Sublethal impacts such as reduced reproduction are nearly impossible to detect without rigorous environmental monitoring. For these reasons, NMFS uses surrogates for the allowable extent of take of listed species, as described below within each of the species groupings.

Anadromous and Marine Fish

NMFS therefore identifies, as a surrogate for the allowable extent of take of anadromous and marine fish, the ability of this action to proceed without any fish kills within the action area attributed to the legal use of chlorpyrifos, diazinon or malathion, or any compounds, degradates, or mixtures affecting aquatic habitats containing listed species. Because of the difficulty of detecting mortality of listed species, individuals killed do not have to be listed species in order for their death to be considered a relevant surrogate for take. For example, salmonids are relatively sensitive to pesticides compared to other species of fish, so that if there are kills of other freshwater fishes attributed to use of these pesticides, it is likely that salmonids have also died, even if no dead salmonids can be located. In addition, if stream conditions due to pesticide use kill less sensitive fishes in certain areas, the potential for lethal and non-lethal takes in downstream areas increases. A fish kill is considered attributable to one of these three ingredients, its metabolites, or degradates, if any of the a.i.s is known to have been applied in the vicinity and may reasonably be supposed to have run off or drifted into the affected area, or if surface water samples or pathology indicate lethal levels of the a.i.(s).

NMFS notes that increased monitoring and study of the impact of these pesticides on water quality, particularly water quality in flood plain habitats, nearshore estuarine, and marine habitats will inform subsequent pesticide consultations and future incidental take statements. Such monitoring and studies will potentially allow other measures of the extent of take.

Marine Invertebrates

NMFS therefore identifies, as a surrogate for the allowable extent of take of marine invertebrates, the ability of this action to proceed without any mortality or adverse reproductive effects to corals or molluscs within the action area attributed to the legal use of chlorpyrifos, diazinon or malathion, or any compounds, degradates, or mixtures affecting aquatic habitats containing listed species. Because of the difficulty of detecting mortality of listed species, individuals killed or adversely affected do not have to be listed species in order for their death or adverse effects to be considered relevant surrogate for take. An adverse effect is considered attributable to one of these three ingredients, its metabolites, or degradates, if any of the a.i.s is known to have been applied in the vicinity and may reasonably be supposed to have run off or drifted into the affected area, or if surface water samples or pathology indicate lethal levels of the a.i.(s).

Sea Turtles

NMFS therefore identifies, as a surrogate for the allowable extent of take sea turtles, the ability of this action to proceed without any mortality or sublethal effects to sea turtles including adverse impacts to swimming or reproduction within the action area attributed to the legal use of chlorpyrifos, diazinon or malathion, or any compounds, degradates, or mixtures affecting aquatic habitats containing listed species. Because of the difficulty of detecting mortality of listed species, individuals killed or adversely affected do not have to be listed species in order for their death or adverse effects to be considered relevant surrogate for take. An adverse effect is considered attributable to one of these three ingredients, its metabolites, or degradates, if any of the a.i.s is known to have been applied in the vicinity and may reasonably be supposed to have run off or drifted into the affected area, or if surface water samples or pathology indicate lethal levels of the a.i.(s).

Pinnipeds
NMFS therefore identifies, as a surrogate for the allowable extent of take of pinnipeds, the ability of this action to proceed without any mortality or adverse impacts to to pinniped swimming or reproduction attributed to the legal use of chlorpyrifos, diazinon or malathion, or any compounds, degradates, or mixtures affecting aquatic habitats containing listed species. Because of the difficulty of detecting mortality or other adverse effects to of listed species, individuals killed or adversely affected do not have to be listed species in order for their death or adverse effects to be considered relevant surrogate for take. An adverse effect is considered attributable to one of these three ingredients, its metabolites, or degradates, if any of the a.i.s is known to have been applied in the vicinity and may reasonably be supposed to have run off or drifted into the affected area, or if surface water samples or pathology indicate lethal levels of the a.i.(s).

Cetaceans - Southern Resident Killer Whale (SRKW)
NMFS therefore identifies, as a surrogate for the allowable take of SRKW, the ability of this action to proceed without any mortality to Pacific Salmonids attributed to the legal use of chlorpyrifos, diazinon, or malathion. Salmon, in particular Chinook salmon, are the prey for SRKW. Currently, the numbers of Chinook and other salmon are insufficient to support increases in the SRKW population size. The reduction in production of Pacific salmon throughout their range that would occur under the Proposed Action would therefore result in harm to SRKW by further reducing prey availability, which may cause animals to forage for longer periods, travel to alternate locations, or abandon foraging efforts. The extent of take from the Proposed Action is not anticipated to cause direct take by serious injury or mortality to SRKWs. However, the Proposed Action is expected to result in take in the form of a reduction in available prey.

26.5 Terms and Conditions

To be exempt from the prohibitions of section 9 of the ESA, the Environmental Protection Agency must comply with the following terms and conditions, which implement the Reasonable and Prudent Measures described above. These include the take minimization, monitoring and reporting measures required by the section 7 regulations (50 C.F.R. §402.14(i)). These terms and conditions are non-discretionary. If the Environmental Protection Agency fails to ensure compliance with these terms and conditions and their implementing reasonable and prudent measures, the protective coverage of section 7(o)(2) may lapse.

To address RPM number 1, EPA shall implement the following revisions on all chlorpyrifos, diazinon, and malathion labels:

a. Prohibit application of pesticide products when wind speeds are greater than or equal to 10 mph.
b. Prohibit application of pesticide products when soil moisture is at field capacity, or when a storm event likely to produce runoff from the treated area is forecasted (by NOAA/National Weather Service, or other similar forecasting service) to occur within 48 hours following application.

c. Prohibit co-application (tank mixing) with other neurotoxic pesticides (i.e., organophosphate, carbamate, pyrethroid, and neonicotinoid pesticides).

To implement RPM number 2, EPA shall:

a) Provide home owner and commercial applicator training on relevant endangered species and designated critical habitats including information on risk reduction measures, best management practices, etc.
b) Report all incidents of mortality and adverse effects to non-target species that occur within the vicinity of the treatment area, including areas downstream and downwind, in the four days following application of and of these a.i.s to EPA's Office of Pesticide Programs (phone: 703-305-7090). Within one year of receipt of this Opinion, EPA shall submit an annual report to NMFS Office of Protected Resources that identifies the total number of non-target species affected and incident locations.
c) EPA shall, in close coordination with NMFS Office of Protected Resources, develop and implement an effectiveness monitoring plan for aquatic habitats. A report summarizing annual monitoring data and including all raw data shall be submitted to NMFS Office of Protected Resources and will summarize annual monitoring data and provide all raw data.
d) EPA shall include the following instructions requiring reporting of mortality events either on the labels for all products containing chlorpyrifos, diazinon, and malathion in ESPP Bulletins:

   NOTICE: Incidents where listed species appear injured or killed as a result of pesticide applications shall be reported to NMFS Office of Protected Resources at 301-713-1401 and EPA's Office of Pesticide Programs. The finder should leave the individuals alone, make note of any circumstances likely causing the death or injury, location and number of individuals involved, and take photographs, if possible. Individuals should generally not be disturbed unless circumstances arise where the individual is obviously injured or killed by pesticide exposure, or some unnatural cause. NMFS Office of Protected Resources or Office of Law Enforcement may request the finder to collect specimens or take other measures to ensure that evidence intrinsic to the specimen is preserved.
e) EPA shall report to NMFS Office of Protected Resources any incidences regarding chlorpyrifos, diazinon, and malathion effects on aquatic ecosystems added to its incident database that it has classified as probable or highly probable.
f) EPA shall provide OPR a commencement date for annual reporting of monitoring results.

26.6 Conservation Recommendations

Section 7(a)(1) of the ESA directs Federal agencies to use their authorities to further the purposes of the ESA by carrying out conservation programs for the benefit of the threatened and endangered species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on ESA-listed species or critical habitat, to help implement recovery plans or develop information (50 C.F.R. §402.02).

The following conservation recommendations would provide information for future consultations involving future authorizations of pesticide active ingredients that may affect ESA-listed species:

1. Develop models that more accurately quantify pesticide exposure in estuarine and near-shore ocean environments.
2. Work with other appropriate federal, state, and local partners to determine efficacy of riparian area management methods in reducing pesticide loading from authorized uses especially the types of vegetation and width of riparian areas needed.
3. Identify and implement other methods that eliminate or significantly reduce pesticide loading into species' habitats.
4. Carryout educational outreach on pesticide risks to threatened and endangered species to pesticide users in high use agriculture and residential environments.
5. Develop improved methods for characterizing exposure from non-agricultural uses.
6. Develop criteria that addresses when pesticide-contaminated sediment is an important route of exposure to aquatic organisms.

In order for NMFS' Office of Protected Resources Endangered Species Act Interagency Cooperation Division to be kept informed of actions minimizing or avoiding adverse effects on, or benefiting, ESA-listed species or their critical habitat, the Environmental Protection Agency should notify the Endangered Species Act Interagency Cooperation Division of any conservation recommendations they implement in their final action.

26.7 Reinitiation Notice

This concludes formal consultation for the Environmental Protection Agency's proposed registration of pesticide products containing chlorpyrifos, diazinon, and malathion to ESA-listed species under the jurisdiction of the NMFS. As 50 C.F.R. §402.16 states, reinitiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been retained (or is authorized by law) and if:

1. The amount or extent of taking specified in the incidental take statement is exceeded.
2. New information reveals effects of the agency action that may affect ESA-listed species or critical habitat in a manner or to an extent not previously considered.
3. The identified action is subsequently modified in a manner that causes an effect to ESA-listed species or designated critical habitat that was not considered in this opinion.
4. A new species is listed or critical habitat designated under the ESA that may be affected by the action.

NMFS' analysis and conclusions are based on EPA's action. If changes to product labeling result in modifications to the action that were not considered in this Opinion, including but not limited to label modifications authorizing pesticide application to new locations, additional application methods, or increased application rates or numbers of applications, EPA must contact NMFS to discuss reinitiation. If reinitiation of consultation appears warranted due to one or more of the above circumstances, EPA must contact NMFS Office of Protected Resources, ESA Interagency Cooperation Division. In the event reinitiation conditions (1), (2), or (3) is met, reinitiation will be only for the a.i.(s) which meet that condition, not for all 3 a.i.s considered in the Opinion. If none of these reinitiation triggers are met within the next 15 years, then reinitiation will be required because the Opinion only covers the action for 15 years. It is recommended that EPA request reinitiation with sufficient time prior to reaching 15 years to allow sufficient time to consult and to prevent lapse of coverage for the active ingredients in this Opinion.

A. APPENDIX: MAGTOOL RESULTS FOR LISTED SPECIES

The MagTool (developed by EPA) was used to generate mortality estimates for 30 of the 77 species being consulted on, all of which are anadromous. MagTool estimates were not generated for nine anadromous species due to inaccuracies in the underlying species range data. See Appendix D for additional information regarding the conceptual design of the MagTool, as well as for inputs used by NMFS to generate the estimates provided below.

B. APPENDIX: PACIFIC SALMON POPULATION MODELING

Introduction

To assess the potential for adverse impacts of the anticholinesterase insecticides on Pacific salmon populations, a model was developed that explicitly links impairments in the biochemistry, behavior, prey availability and somatic growth of individual salmon to the productivity of salmon populations. More specifically, the model connects known effects of the pesticides on salmon physiology and behavior with community-level effects on salmon prey to estimate population-level effects on salmon. The model used here is an extension of one developed for investigating the direct effects of pesticides on the biochemistry, behavior and growth of ocean-type Chinook salmon (Baldwin et al., 2009) and includes indirect impacts on prey base (Macneale et al, 2014).

In the freshwater portion of their life, Pacific salmon may be exposed to insecticides that act by inhibiting acetylcholinesterase (AChE). Acetylcholinesterase is a crucial enzyme in the proper functioning of cholinergic synapses in the central and peripheral nervous systems of vertebrates and invertebrates. Of consequence to salmon, anticholinesterase insecticides have been shown to interfere with salmon swimming behavior (Beauvais et al. 2000, Brewer et al. 2001, Sandahl et al. 2005), feeding behavior (Sandahl et al. 2005), foraging behavior (Morgan and Kiceniuk 1990), homing behavior (Scholz et al. 2000), antipredator behaviors (Scholz et al. 2000) and reproductive physiology (Moore and Waring 1996, Waring and Moore 1997, Scholz et al. 2000).

Anticholinesterase insecticides also reduce benthic densities of aquatic invertebrates and alter the composition of aquatic communities (Liess and Schulz 1999, Schulz and Liess 1999, Schulz et al. 2002, Fleeger et al. 2003, Schulz 2004, Chang et al. 2005, Relyea 2005). Spray drift and runoff from agricultural and urban areas can expose aquatic invertebrates to relatively low concentrations of insecticides for as little as minutes or hours, but populations of many taxa can take months or even years to recover to pre-exposure or reference densities (Wallace et al. 1991, Liess and Schulz 1999, Anderson et al. 2003, Stark et al. 2004). For example, when an aquatic macroinvertebrate community in a German stream was exposed to runoff containing parathion (an acetylcholinesterase inhibitor) and fenvalerate (another commonly used insecticide), eight of eleven abundant species disappeared and the remaining three were reduced in abundance (Liess and Schulz 1999). Long-term changes in invertebrate densities and community composition likely result in reductions in salmon prey availability. Therefore, in addition to the direct impacts that acetylcholinesterase inhibitors have on salmon, there may also be, independently, significant indirect effects to salmon via their prey (Peterson et al. 2001a). Wild juvenile salmon feed primarily on invertebrates in the water column and those trapped on the water's surface, actively selecting the largest items available (Healey 1991, Quinn 2005). Salmon are often found to be food limited (Quinn 2005), suggesting that a reduction in prey number or size due to insecticide exposure may further stress salmon. For example, Davies and Cook (1993) found that several months following a spray drift event, benthic and drift densities were still reduced in exposed stream reaches. Consequently, brown trout in the exposed reaches fed less and grew at a slower rate compared to those in unexposed stream reaches (Davies and Cook 1993). Although the insecticide in their study was cypermethrin (a pyrethroid), similar reductions in macroinvertebrate density and recovery times have been found in studies with acetylcholinesterase inhibitors (Liess and Schulz 1999, Schulz et al. 2002), suggesting indirect effects to salmon via prey availability may be similar.

One likely biological consequence of reduced swimming, feeding, foraging, and prey availability is a reduction in food uptake and, subsequently, a reduction in somatic growth of exposed fish. Juvenile growth is a critical determinant of freshwater and marine survival for Chinook salmon (Higgs et al. 1995). Reductions in the somatic growth rate of salmon fry and smolts are believed to result in increased size-dependent mortality (Healey 1982, West and Larkin 1987, Zabel and Achord 2004). Zabel and Achord (2004) observed size-dependent survival for juvenile salmon during the freshwater phase of their outmigration. Mortality is also higher among smaller and slower growing salmon because they are more susceptible to predation during their first winter (Healey 1982, Holtby et al. 1990, Beamish and Mahnken 2001). These studies suggest that factors affecting the organism and reducing somatic growth, such as anticholinesterase insecticide exposure, could result in decreased first-year survival and, thus, reduce population productivity.

Changes to the size of juvenile salmon from exposure to anticholinesterase pesticides were linked to salmon population demographics (Baldwin et al., 2009). We used size-dependent survival of juveniles during a period of their first year of life. We did this by constructing and analyzing general life-history matrix models for coho salmon (*Oncorhynchus kisutch*), sockeye salmon (*O. nerka*) and ocean-type and stream-type Chinook salmon (*O. tshawytscha*). A steelhead (*O. mykiss*) life-history model was not constructed due to the lack of demographic information relating to the proportions of resident and anadromous individuals, the freshwater residence time of steelhead, and rates of repeated spawning. The basic salmonid life history modeled consisted of hatching and rearing in freshwater, smoltification in estuaries, migration to the ocean, maturation at sea, and returning to the natal freshwater stream for spawning followed shortly by death. Differences between the modeled strategies are lifespan of the female, time to reproductive maturity, and the number and relative contribution of the reproductive age classes (Figure A1-1). The coho females we modeled reach reproductive maturity at age 3 and provide all of the reproductive contribution. Sockeye females reach maturity at age 4 or 5, but the majority of reproductive contributions are provided by age 4 females. Chinook females can mature at age 3, 4 or 5, with the majority of the reproductive contribution from ages 4 and 5. The primary difference between the ocean-type and stream-type Chinook is the juvenile freshwater residence with ocean-type juveniles migrating to the ocean as subyearlings and stream-type overwintering in freshwater and migrating to the ocean as yearlings. The models depicted general populations representing each life-history strategy and were constructed based upon literature data described below. Specific populations were not modeled due to the lack of sufficient demographic and reproductive data for a single population.

A separate acute toxicity model was constructed that estimated the population-level impacts of juvenile mortality resulting from exposure to lethal concentrations of chlorpyrifos, diazinon and malathion. These models excluded sublethal and indirect effects of the pesticide exposures and focused on the population-level outcomes resulting from an annual exposure of juveniles to a pesticide. The lethal impact was implemented as a change in first year survival for each of the salmon life-history strategies.

The overall model endpoint used to assess population-level impacts for both the growth and acute lethality models was the percent change in the intrinsic population growth rate (lambda, λ) resulting from the pesticide exposure. Change in λ is an accepted population parameter often used in evaluating population productivity, status, and viability. The National Marine Fisheries Service uses changes in λ when estimating the status of species, conducting risk and viability assessments, developing Endangered Species Recovery Plans, composing Biological Opinions, and communicating with other federal, state and local agencies (McClure et al. 2003). While values of $\lambda<1.0$ indicate a declining population, negative changes in lambda greater than the natural variability for the population indicate a loss of productivity. This can be a cause for concern since the decline could make a population more susceptible to dropping below 1.0 due to impacts from multiple stressors.

The following models were developed to serve as a means to assess the potential effects on ESA-listed salmon populations from exposure to AChE inhibiting pesticides, including n-methyl carbamates and organophosphorus insecticides. The growth model focuses on the impacts to prey abundance and a salmon's ability to feed which are integrated into reductions in juvenile growth. Assessing the results from different pesticide exposure scenarios relative to a control (i.e. unexposed) scenario can indicate the potential for sublethal pesticide exposures to lead to changes in the somatic growth and survival of individual subyearling salmon. Consequently, subsequent changes in salmon population dynamics as indicated by percent change in a population's intrinsic rate of increase assists in forecasting the potential population-level impacts to listed populations. Also, the model helps us understand the potential influence of life-history strategies that might explain differential results within the species modeled.

Methods

The somatic growth model consists of two parts, an organismal portion and a population portion. The organismal portion of the model links AChE inhibition and reduced prey abundance due to insecticide exposure to potential reductions in the growth of individual fish. The population portion of the model links the sizes of individual subyearling salmon to their survival and the subsequent growth of the population. Models were constructed using MATLAB 7.7.0 (R2008b) (The MathWorks, Inc. Natick, MA).

Organismal Model

The organismal model tracks individual somatic growth of salmonid fingerlings using a series of relationships between pesticide exposure, AChE activity, feeding behavior, food uptake, and somatic growth rate (Figures A1-2-4). The model incorporates empirical data when available (Baldwin et al., 2009). Since growth and toxicity data are limited, extrapolation from one salmon species to the others was done with the assumption that the salmon stocks would exhibit similar physiological and toxicological responses. Sigmoidal dose-response relationships based upon the AChE inhibition EC50 values and their slopes are used to determine the level of AChE activity (Figure A1-2A, 2B, 2C) from the exposure concentration of each pesticide exposure or pulse.

A linear relationship based on empirical data related AChE activity to feeding behavior (Sandahl et al. 2005, Figure A1-2D). Feeding behavior was then assumed to be directly proportional to food uptake, defined as potential ration (Figure A1-2E, Brett 1969). The potential ration expresses the amount of food the organism can consume when prey abundance is not limiting. Potential ration over time (Figure A1-2F) depicts how the food intake of individual fish changes in response to the behavioral effects of the pesticide exposure over the modeled growth period. Potential ration is equal to final ration if no effects on prey abundance are incorporated (Figure A1-4). When effects of pesticide exposure on prey abundance are incorporated, final ration is the product of potential ration (relating to the fish's ability to capture prey, Figure A1-2) and the relative abundance of prey available following exposure (Figure A1-3). Next, additional empirical data (e.g. Weatherley and Gill 1995) defined the relationship between final ration and somatic growth rate (Figure A1-4C). While the empirical relationship is more complex (e.g. somatic growth rate plateaus at rations above maximum feeding), a linear model was considered sufficient for the overall purpose of this model. Finally, the model combines these linear models relating AChE activity to feeding behavior, feeding behavior to potential ration, and final ration to somatic growth rate to produce a linear relationship between AChE activity and somatic growth rate (Figure A1-4D). One important assumption of the model is that the relationships are stable, i.e. do not change with time. The relationships would need to be modified to incorporate time as a variable if, for example, fish are shown to compensate over time for reduced AChE activity to improve their feeding behavior and increase food uptake.

The models allow exposures that can include multiple AChE-inhibiting pesticides over various time pulses. Sigmoidal dose-response relationships, at steady-state, between each single pesticide exposure and 1) AChE activity and 2) relative prey abundance are modeled using specific EC50s and EC50s and slopes (Figure A1-2B and 3B). The timecourse for each exposure was built into the model as a pulse with a defined start and end during which the exposure remained constant (Figure A1-2A and 3A). The timecourse for AChE activity, on the other hand, was modeled using two single-order exponential functions, one for the time required for the exposure to reach full effect and the other for time required for complete recovery following the end of the exposure (time-to-effect$_{\text{AChE activity}}$ and time-to-recovery$_{\text{AChE activity}}$, respectively; Figure A1-2C). The apparent activity level was back-calculated to result in a relative concentration (concentration/ AChE inhibition EC50) for each day of the growth period for each pulse. The relative concentration for each day was summed across all the pulses to result in a total apparent concentration for each day. The sigmoid slope used in the calculation of AChE activity using the apparent concentration was the arithmetic mean of the sigmoid slopes for each pesticide present on each day. The timecourse for relative prey abundance was modeled incorporating a one day spike in prey drift relative to the toxicity and available prey base followed by a drop in abundance due to the toxic impacts (Figure A1-3C). Recovery is assumed to be due to a constant influx of invertebrates from connected habitats (aquatic and terrestrial) that are not exposed to the pesticide. Incoming organisms are subject to toxicity if pesticides are still present and this alters the rate of recovery during exposures. Incorporating dynamic effects and recovery variables allows the model to simulate differences in the pharmacokinetics (e.g. the rates of uptake from the environment and of detoxification) of various pesticides and simulate differences in invertebrate community response and recovery rates (see below).

The relationship between final ration and somatic growth rate (Figure A1-4C) produces a relationship representing somatic growth rate over time (Figure A1-4D), which is then used to model individual growth rate and size over time. The growth models were run for 1000 individual fish, with initial weight selected from a normal distribution with a mean of 1.0 g and standard deviation of 0.1 g. The size of 1.0 g was chosen to represent subyearling size in the spring prior to the onset of pesticide application. For each iteration of the model (one day for the organismal model), the somatic growth rate is calculated for each fish by selecting the parameter values from normal distributions with specified means and standard deviations (Table A1-1). The weight for each fish is then adjusted based on the calculated growth rate to generate a new weight for the next iteration. The length (days) to run the growth portion of the model was selected to represent the time from when the fish enter the linear portion of their growth trajectory in the mid to late spring until they change their growth pattern in the fall due to reductions in temperature and resources or until they migrate out of the system. The outputs of the organismal model that are handed to the population models consist of mean weights (with standard deviations) after the species-appropriate growth period (Table A1-2). A sensitivity analysis was run to determine the influence of the parameter values on the output of the growth model.

The option of exposing only a specified percent of the population to the pesticide(s) during the somatic growth period is provided. The exposed percent of the population is applied to the number of individuals run in the individual growth model. After running all 1000 individual growth trajectories (with X% exposed and 100-X% control) the mean weight and standard deviation of the whole is determined and handed to the population model to run as the size distribution of the impacted population.

The parameter values defining control conditions that are constant for all the modeled species are listed in Table A1-1. Model parameters such as the length of the growth period and control daily growth rate that are species specific are listed in Table A1-2. Each exposure scenario was defined by a concentration and exposure time for each pesticide. The duration of time until full effect for the pesticides was assumed to be within a few days (Ferrari et al. 2004), with a half-life of 0.5 days. Toxicity values describing 50% inhibition of AChE activity (IC_{50}) and the sigmoid slope for each active ingredient are shown in Table A1-3, as reported in the chlorpyrifos, malathion, and diazinon biological evaluations (EPA 2017).

The effects of exposures on the prey base are incorporated in the somatic growth model as the available ration (Macneale et al., 2014). For prey, it is assumed there is a constant, independent influx of prey from upstream habitats that will eventually (depending on the rate selected) return prey abundance to 1. As mentioned above, however, these invertebrates are subject to exposure once added to the system, and therefore prey recovery rate is a product of the influx rate as well as the exposure scenario. While recovery rates reported in the literature vary, it is assumed a 1% recovery rate is ecologically realistic (Ward et al. 1995, Van den Brink et al. 1996, Colville et al. 2008). It was also assumed that regardless of the exposure scenario, relative prey abundance would not drop below a specific floor (Figure A1-3B). This assumption depends on a minimal yet constant terrestrial subsidy of prey and/or an aquatic community with tolerant individuals that would be available as prey, regardless of pesticide exposure and in addition to the constant recovery rate. No studies specify floors per se, but studies quantifying invertebrate densities following highly toxic exposures indicate a floor of 0.2 is ecologically realistic (i.e. regardless of the exposure, 20% of a fish's ration will be available daily; e.g., Cuffney et al. 1984). Finally, because prey availability has been found to increase dramatically albeit briefly following pesticide exposures (due to immediate mortality and/or emigration of benthic prey into the water column; Davies and Cook 1993, Schulz 2004), a one-day prey spike is included for the day following an exposure. The relative magnitude of the spike is calculated as the product of the standing prey availability the day prior to exposure (minus the floor), the toxicity of the exposure, and a constant of 20. This calculation therefore accounts for the potential prey that are available and the severity of the exposure. The spike will be greater when more prey are available and/or the toxicity of the exposure is greater; alternatively, the spike will be small when few prey are available and/or the exposure toxicity is low. The toxicity values for prey abundance (EC_{50} and sigmoid slope) were calculated as the lower 5^{th} percentile of the invertebrate species sensitivity distribution from the USEPA BE (Table A1-3).

Below are the mathematical equations used to derive Figures A1-2, 3, and 4.

Figures A1-2A and 3A use a step function:

time < start; exposure = 0
start ≤ time ≤ end; exposure = exposure concentration(s)
time > end; exposure = 0.

Figures A1-2B and 3B use a sigmoid function:

y = bottom + (top – bottom)/(1 + (exposure concentration/EC50)^slope).
For 2B, y = AChE activity, top = Ac, bottom = 0.
For Figure 3B, y = prey abundance, top = Pc (in this case 1), bottom = Pf.

Figures A1-2D, 2E, and 4C use a linear function (the point-slope form of a line):

y = m*(x – x1) + y1.
For 2D, m = Mfa, x1 = Ac, and y1 = Fc.
For 2E, m = Mrf (computed as Rc/Fc), x1 = Fc, and y1 = Rc.
For 4C, m = Mgr, x1 = Rc, and y1 = Gc.

Figure A1-2C uses a series of exponential functions:

time < start; y = c
start ≤ time ≤ end; y = c – (c – i)*(1 – exp(-ke*(time – start)))
time > end; ye = c – (c – i)*(1 – exp(-ke*(end – start)))
y = ye + (c – ye)*(1 – exp(-kr*(time – end))).

For Figure 2C, c = Ac, i = Ai, ke = ln(2)/AChE effect half-life, kr = ln(2)/AChE recovery half-life. For Figure 2C the value of ye is calculated to determine the amount of inhibition that is reached during the exposure time, which may not be long enough to reach the maximum level of inhibition.

For Figure A1-3C, an exposure pulse would result in a 1-day spike followed by a decline to the impacted level based upon the prey toxicity. During exposures resulting in low prey toxicity, toxicity-limited recovery can occur. After exposure ends, a constant rate of recovery proceeds until control drift is reached or another exposure occurs

preyavail=preydrift(day-1)-floor;
preytox=1/(1+(concentration)^preyslope);
preyrecrate=0.01;
preydriftrec = preyrecrate*preytox.

time=start; spike=(-1+10^(1.654*preyavail))*(1-preytox)
preydrift =preydrift+spike
start ≤ time ≤ end; preydrift=(preyavail*preytox)+preyrdriftrec+floor;
time>end; preydrift = preydrift(day-1)+preydriftrec

Figure A1-2F is generated by using the output of Figure A1-2C for a given time as the input for 2D and using the resulting output of 2D as the input for 2E. The resulting output of 2E produces a single time point in the relationship in 2F. Performing this series of computations across multiple days produces the entire relationship in 2F. 4D is generated by taking the outputs of 4A and 4B for the same day. Note the relationship of 4A is equivalent to 2F. The resulting outputs of 4A and 4B are multiplied to produce a final ration for a given day. The prey abundance (4B) available for consumption during a prey spike is capped at a maximum of 1.5*control drift to provide a limited benefit to the individual fish. The final ration is used as input for 4C to generate 4D.

Salmonid Population Model

The weight distributions from the organismal growth portion of the model are used to calculate size-dependent first-year survival for a life-history matrix population model for each species and life-history type. This incorporates the impact that reductions in size could have on population growth rate and abundance. The first-year survival element of the transition matrix incorporates a size-dependent survival rate for a three- or four-month interval (depending upon the species) which takes the subyearlings up to 12 months of age. This time represents the 4-month early winter survival in freshwater for stream-type Chinook, coho, and sockeye models. For ocean-type Chinook, it is the 3-month period the subyearling smolt spend in the estuary and nearshore habitats (i.e. estuary survival). The weight distributions from the organismal model are converted to length distributions by applying condition factors from data for each modeled species (cf; 0.0095 for sockeye and 0.0115 for all others) as shown in Equation L.

Equation L: length(mm) = ((fish weight(g)/cf)^(1/3))*10

The relationship between length and early winter or estuary survival rate was adapted from Zabel and Achord (2004) to match the survival rate for each control model population (Howell et al. 1985, Kostow 1995, Myers et al. 2006). The relationship is based on the length of a subyearling salmon relative to the mean length of other competing subyearling salmon of the same species in the system, Equation D, and relates that relative difference to size-dependent survival based upon Equation S. The values for α and resulting size-dependent survival (survival ϕ) for control runs for each species are listed in Table A1-2. The constant α is a species-specific parameter defined such that it produces the correct control survival ϕ value when Δlength equals zero.

Equation D: $\Delta\text{length} = \text{fish length(mm)} - \text{mean length(mm)}$

Equation S: $\text{Survival } \phi = (e^{(\alpha+(0.0329*\Delta\text{length}))}) / (1 + e^{(\alpha+(0.0329*\Delta\text{length}))})$

Randomly selecting length values from the normal distribution calculated from the organismal model output size and applying equations 1 and 2 generates a size-dependent survival probability for each fish. This process was replicated 1000 times for each exposure scenario and simultaneously 1000 times for the paired control scenario and results in a mean size-dependent survival rate for each population. The resulting size-dependent survival rates are inserted in the calculation of first-year survival in the respective control and pesticide-exposed transition matrices.

The investigation of population-level responses to pesticide exposures uses life-history projection matrix models. Individuals within a population exhibit various growth, reproduction, and survivorship rates depending on their developmental or life-history stage or age. These age specific characteristics are depicted in the life-history graph (Figure A1-1A-D) in which transitions are depicted as arrows. The nonzero matrix elements represent transitions corresponding to reproductive contribution or survival, located in the top row and the subdiagonal of the matrix, respectively (Figure A1-1E). The survival transitions in the life-history graph are incorporated into the n x n square matrix (A) by assigning each age a number (1 through n) and each transition from age i to age j becomes the element a_{ij} of matrix A (i = row, j = column) and represent the proportion of the individuals in each age passing to the next age as a result of survival. The reproductive element (a_{1j}) gives the number of offspring that hatch per individual in the contributing age, j. The reproductive element value incorporates the proportion of females in each age, the proportion of females in the age that are sexually mature, fecundity, fertilization success, and hatch success.

In order to understand the relative impacts of a short-term pesticide exposure on exposed vs. unexposed fish, we used parameters for an idealized baseline population that exhibits an increasing population growth rate. All characteristics exhibit density independent dynamics. There were no definitive data available on the populations to support specific density dependent relationships, so rather than assign an unsupported relationship, the NAS recommendation was followed to utilize density independent parameters. The models assume closed systems, allowing no migration impact on population size. No stochastic impacts are included beyond natural variability as represented by selecting parameter values from a normal distribution about a mean each model iteration (year). Ocean conditions, freshwater habitat, fishing pressure, and marine resource availability were assumed constant and density independent so that they remain in the range they occupied during the period when demographic data were collected.

In the model an individual fish experiences an exposure scenario once as a subyearling (during its first spring) and never again. The pesticide exposure is assumed to occur annually. All individuals in one cohort within a given population are assumed to be exposed to the pesticide during their subyearling spring-summer growth period. No other age classes experience the exposure. Regardless of the level of AChE inhibition due to the direct exposure, only the sublethal effects related to somatic growth are incorporated in the models.

The model recalculates first-year survival for each run using a size-dependent survival value selected from a normal distribution with the mean and standard deviation produced by Equation S. Population model output consists of the percent change in lambda from the unexposed control populations derived from the mean of two thousand calculations of both the unexposed control population and the pesticide exposed population. Change in lambda, representing alterations to the population productivity, was selected as the primary model output for reasons outlined previously.

A prospective analysis of the transition matrix, A, (Caswell 2001) explored the intrinsic population growth rate as a function of the vital rates. The intrinsic population growth rate, λ, equals the dominant eigenvalue of A and was calculated using matrix analysis software (MATLAB version 7.7.0 by The Math Works Inc., Natick, MA). Therefore λ is calculated directly from the matrix and running projections of abundances over time is redundant and unnecessary. The stable age distribution, the proportional distribution of individuals among the ages when the population is at equilibrium, is calculated as the right normalized eigenvector corresponding to the dominant eigenvalue λ. Variability was integrated by repeating the calculation of λ 2000 times selecting the values in the transition matrix from their normal distribution defined by the mean standard deviation. The influence of each matrix element, a_{ij}, on λ was assessed by calculating the sensitivity values for A. The sensitivity of matrix element a_{ij} equals the rate of change in λ with respect to a_{ij}, defined by $\delta\lambda / \delta a_{ij}$. Higher sensitivity values indicate greater influence on λ. The elasticity of matrix element a_{ij} is defined as the proportional change in λ relative to the proportional change in a_{ij}, and equals (a_{ij}/λ) times the sensitivity of a_{ij}. One characteristic of elasticity analysis is that the elasticity values for a transition matrix sum to unity (one). The unity characteristic also allows comparison of the influence of transition elements and comparison across matrices.

Due to differences in the life-history strategies, specifically lifespan, age at reproduction and first year residence and migration habits, four life-history models were constructed. This was done to encompass the different responses to freshwater pesticide exposures and assess potentially different population-level responses. Separate models were constructed for coho, sockeye, ocean-type and stream-type Chinook. In all cases, transition values were determined from literature data on survival and reproductive characteristics of each species for populations that exhibit the life history strategy and were listed as endangered, threatened, or a species of concern under the ESA. All transition values are listed in Table A1-4.

A life-history transition matrix was constructed for coho salmon (*O. kisutch*) with a maximum age of 3. Spawning occurs in late fall and early winter with emergence from March to May. Fry spend 14-18 months in freshwater, smolt and spend 16-20 months in the saltwater before returning to spawn (Pess et al. 2002). Survival numbers were summarized in Knudsen et al. (2002) as follows. The average fecundity of each female is 4500 with a standard deviation of 500. The observed number of males:females was 1:1. Survival from spawning to emergence is 0.3 (0.07). Survival from emergence to smolt is 0.0296 (0.00029) and marine survival is 0.05 (0.01). All parameters followed a normal distribution (Knudson et al. 2002). The calculated values used in the matrix are listed in Table A1-4. The growth period for first year coho was set at 180 days to represent the time from mid-spring to mid-fall when the temperatures and resources drop and somatic growth slows (Knudson et al. 2002).

The life-history matrix for sockeye salmon (*O. nerka*) were based upon the lake wintering populations of Lake Washington, Washington, USA. These female sockeye salmon spend one winter in freshwater, then migrate to the ocean to spend three to four winters before returning to spawn at ages 4 or 5. Jacks return at age 2 after only one winter in the ocean. The age proportion of returning adults is 0.03, 0.82, and 0.15 for ages 3, 4 and 5, respectively (Gustafson et al.1997). All age 3 returning adults are males. Hatch rate and first year survival were calculated from brood year data on escapement, resulting presmolts and returning adults (Pauley et al. 1989) and fecundity (McGurk 2000). Fecundity values for age 4 females were 3374 (473) and for age 5 females were 4058 (557) (McGurk 2000). First year survival rates were 0.737/month (Gustafson et al. 1997). Ocean survival rates were calculated based upon brood data and the findings that 90% of ocean mortality occurs during the first 4 months of ocean residence (Pauley et al. 1989). Matrix values used in the sockeye baseline model are listed in Table A1-4. The 168 day growth period represents the time from lake entry to early fall when the temperature drops and somatic growth slows (Gustafson et al. 1997).

A life-history matrix was constructed for ocean-type Chinook salmon (*O. tshawytscha*) with a maximum female age of 5 and reproductive maturity at ages 3, 4 or 5. Ocean-type Chinook migrate from their natal stream within a couple months of hatching and spend several months rearing in estuary and nearshore habitats before continuing on to the open ocean. Transition values were determined from literature data on survival and reproductive characteristics from several ocean-type Chinook populations in the Columbia River system (Healey and Heard 1984, Howell et al. 1985, Roni and Quinn 1995, Ratner et al. 1997, PSCCTC 2002, Green and Beechie 2004). The sex ratio of spawners was approximately 1:1. Estimated size-based fecundity of 4511(65), 5184(89), and 5812(102) was calculated based on data from Howell et al., 1985, using length-fecundity relationships from Healy and Heard (1984). Control matrix values for the Chinook model are listed in Table A1-4. The growth period of 140 days encompasses the time the fish rear in freshwater prior to entering the estuary and open ocean. The first three months of estuary/ocean survival are the size-dependent stage. Size data for determining subyearling Chinook condition indices came from data collected in the lower Columbia River and estuary (Johnson et al. 2007).

An age-structured life-history matrix for stream-type Chinook salmon with a maximum age of 5 was defined based upon literature data on Yakima River spring Chinook from Knudsen et al. (2006) and Fast et al. (1988), with sex ratios of 0.035, 0.62 and 0.62 for females spawning at ages 3, 4, and 5, respectively. Length data from Fast et al. (1988) was used to calculate fecundity from the length-fecundity relationships in Healy and Heard (1984). The 184-day growth period produces control fish with a mean size of 96mm, within the observed range documented in the fall prior to the first winter (Beckman et al. 2000). The size-dependent survival encompasses the 4 early winter months, up until the fish are 12 months old.

Acute Toxicity Model

In order to estimate the population-level responses of exposure to lethal pesticide concentrations, acute mortality models were constructed based upon the control life-history matrices described above. The acute responses are modeled as direct reduction in the first year survival rate (S1). Two options are available to run, direct mortality estimates and exposure scenarios. Direct mortality can be input as percent mortality and is multiplied by the first-year survival rate in the transition matrix. Exposures are assumed to result in a cumulative reduction in survival as defined by the concentration and the dose-response curve as defined by the LC_{50} and slope for each pesticide. A sigmoid dose-response relationship is used to accurately handle responses well away from LC_{50} and to be consistent with other does-response relationships. The model inputs for each scenario are the exposure concentration and acute fish LC_{50}, as well as the sigmoid slope for the LC_{50} from the USEPA BE (Table A1-3). For a given concentration, a pesticide survival rate (1-mortality) is calculated and is multiplied by the control first-year survival rate, producing an exposed scenario first-year survival for the life-history matrix. The model allows for a specified percentage of the population (0-100%) to experience the exposure. A uniform distribution of percentage impacted scenarios were run to explore the effects of this variable (25%, 50%, 75%, 100%). Demographic variability is incorporated as described above using mean and standard deviation of normally distributed survival and reproductive rates and model output consists of the percent change in lambda from unexposed control populations derived from the mean of 10000 calculations of both the unexposed control population and the pesticide exposed population. For the purposes of this assessment, the percent change in lambda is defined as different from control when the difference between the mean percent change is greater than the percent of one standard deviation from the control lambda.

Results

Sensitivity Analysis

A sensitivity analysis conducted on the organismal model revealed that changes in the control somatic growth rate had the greatest influence on the final weights (Table A1-1). While this parameter value was experimentally derived for another species (sockeye salmon; Brett et al. 1969), this value was adapted for each model species and is within the variability reported in the literature for other salmonids (reviewed in Weatherley and Gill 1995). Other parameters related to the daily growth rate calculation, including the growth to ration slope (Mgr) and the control ration produced strong sensitivity values. Initial weight, the prey recovery rate and the prey floor also strongly influenced the final weight values (Table A1-1). Large changes (0.5 to 2X) in the other key parameters produced proportionate changes in final weight.

The sensitivity analysis of all four of the control population matrices predicted the greatest changes in population growth rate (λ) result from changes in first-year survival. Parameter values and their corresponding sensitivity values are listed in Table A1-4. The elasticity values for the transition matrices also corresponded to the driving influence of first-year survival, with contributions to lambda of 0.33 for coho, 0.29 for ocean-type Chinook, 0.25 for stream-type Chinook, and 0.24 for sockeye.

Model Output

Organismal and population model outputs for all growth model scenarios are shown in Tables A1-5-7 and Figure A1-5. Toxicity values were taken from EPA's Biological Evaluations (EPA 2017). The factors driving the level of change in lambda were the Prey Drift and relative AChE Activity parameters determined by the toxicity values for each pesticide (Table A1-3). Increases in direct mortality during the first year of life produced large impacts on the population growth rates for all the life-history strategies (Tables A1-8-19, Figures A1-6-9).

While strong trends in effects were seen for each pesticide across all four life-history strategies modeled, some slight differences were apparent. The similarity in patterns likely stems from using the same toxicity values for all four salmon, while the differences are consequences of distinctions between the life-history matrices. The stream-type Chinook and sockeye models produced very similar results as measured as the percent change in population growth rate. The ocean-type Chinook and coho models output produced the greatest changes in lambda resulting from the pesticide exposures. When looking for similarities in parameters to explain the ranking, no single life history parameter or characteristic, such as lifespan, reproductive ages, age distribution, lambda and standard deviation, or first-year survival show a pattern that matches this consistent output. Combining these factors into the transition matrix for each life-history and conducting the sensitivity and elasticity analyses revealed that changes in first-year survival produced the greatest changes in lambda. In addition, the elasticity analysis can be used to predict relative contribution to lambda from changes in first-year survival on a per unit basis. As detailed by the elasticity values reported above, the same change in first-year survival will produce a slightly greater change in the population growth rate for coho and ocean-type Chinook than for stream-type Chinook and sockeye. While some life-history characteristics may lead a population to be more vulnerable to an impact, the culmination of age structure, survival and reproductive rates as a whole strongly influences the population-level response.

The percent changes in lambdas increased as concentrations of the three organophospates increased. Increases in direct mortality during the first year of life produced large impacts on the population growth rates for all the life-history strategies. Model results for stream-type Chinook salmon showed significant impacts at lower concentrations than the other modeled populations. This result is primarily due to the size of the standard deviation of the unexposed population. Percent changes in lambda were deemed significant if they were outside of one standard deviation from the unexposed population. The relative sensitivity of the life-history models producing the greatest to the least changes in population growth rate for equivalent impact on survival rates was coho salmon, ocean-type Chinook salmon, stream-type Chinook salmon, and sockeye salmon. We note that the choice of LC_{50} is an important driver for these results. Therefore, an LC_{50} above or below the ones used here will result in a different dose-response. However, if the actual environmental 96 hour LC_{50} is lower, then the model will under predict mortality. If the actual environmental acute LC_{50} is higher, then the model will over-predict mortality.

These results indicate that exposure of salmonid populations to chlorpyrifos, diazinon, and malathion for four days at the reported LC_{50}s would have consequences to the population’s growth rate. If exposure occurred every year for each new cohort, population abundance would decline and recovery efforts would be slowed. For each of the combinations of species, insecticide, and percent of the population exposed, we denoted the relative concentration at which the percent change in lambda is deemed significantly different from the unexposed populations.

When we compare the model output concentrations to expected levels in salmonid habitats described in the exposure section, it is likely that some individuals within a population will be exposed during their freshwater juvenile lifestage, particularly those juveniles exposed while utilizing off-channel habitats. The likelihood of population effects from death of juveniles increases for those populations that spend longer periods in freshwaters such as stream-type Chinook, sockeye, and coho salmon. For those populations with lambdas greater than one, reductions in lambda from death of subyearlings can also lead to consequences to abundance and productivity. Attainment of recovery and time-associated goals would likely not be met for populations with reduced lambdas. For those natural populations with current lambdas of less than one, risk of extinction would increase substantially, especially if several successive generations were exposed.Many of the populations that are categorized as core populations or are important to individual strata, have lambdas just above one and are essential to survival and recovery goals. Slight changes in lambda, even as small as 3-4%, would result in reduced abundances and increased time to meet population recovery goals. For those natural populations with current lambdas of less than one, risk of extinction would increase, especially if several successive generations were exposed.

We integrated two avenues of effect to subyearling salmonids' growth from exposure to the three organophosphates. The first avenue is a result of AChE inhibition on the feeding success and subsequent effects to growth of juvenile salmonids. Study results with juvenile salmonids show that feeding success is reduced following exposures to AChE inhibitors (Sandahl, Baldwin et al. 2005). Salmon are often food limited in freshwater aquatic habitats, suggesting that a reduction in prey due to insecticide exposure may further stress salmon and lead to reduced growth rates. Field mesocosm data support this assertion, showing reduced growth of juvenile fish following exposure to the AChE inhibitor, chlorpyrifos (Brazner and Kline 1990). Furthermore, based on our review of the sensitivities of aquatic invertebrates to the three insecticides, we expect reductions in densities and altered composition of the salmonid prey communities. Therefore, the second avenue the model addresses the potential for reductions in juvenile growth due to reductions in available prey.

Reductions in aquatic prey are included in the model because of the high relative toxicity of pesticides to salmonid prey and the extended duration of effects on prey communities. Juvenile salmonids are largely opportunistic, feeding on a diverse community of aquatic and terrestrial invertebrate taxa that are entrained in the water column or on the surface (Higgs, Macdonald et al. 1995). As a group, these invertebrates are among the more sensitive taxa for which there is toxicity data, but within this group, there is a wide range of sensitivities. The three insecticides are highly toxic to aquatic macroinvertebrates; concentrations that are not expected to kill salmonids are often lethal for their invertebrate prey. In particular, prey items that are preferred by small juvenile salmonids (including midge larvae, water fleas, mayflies, caddisflies, and stoneflies) are among the most sensitive aquatic macroinvertebrates. In addition, effects on the prey community can persist for extended periods of time (weeks, months, years), resulting in effects on fish feeding and growth long after an exposure has ended (Ward, Arthington et al. 1995; Van den Brink, van Wijngaarden et al. 1996; Liess and Schulz 1999; Colville, Jones et al. 2008).

These results show that all four species can be severely affected by changes in juvenile growth resulting from AChE inhibition and reduced prey availability. The concentrations that elicit reductions in lambdas are expected to occur in salmonid habitats. The degree to which an actual threatened or endangered population is affected will depend on a host of factors including the number of individuals exposed, the duration of exposure, when they are exposed, and if they are exposed more than once. It is also important to realize that these are idealized populations and we did not incorporate other factors that can affect the sensitivity of exposed salmonids such as elevated temperatures, presence of mixtures of OPs and carbamates, and the condition of the fish. We also did not incorporate incidences of death due to acute toxicity in the growth model. We show however, that even without these other stressors taken into account there is strong evidence that given the expected concentrations in salmonid habitats that populations will be adversely affected if juvenile life stages are exposed.

Table A1-1. List of values used for control parameters to model organismal growth and the model sensitivity to changes in the parameter.

Parameter	Value[1]	Error[2]	Sensitivity[3]
acetylcholinesterase activity (Ac)	1.0[4,5]	0.06[5]	-0.167
feeding (Fc)	1.0[4,5]	0.05[5]	0.088
ration (Rc)	5% weight/day[6]	0.05[7]	-0.547
feeding vs. activity slope (Mfa)	1.0[5]	0.1[5]	-0.047
ration vs. feeding slope (Mrf)	5 (Rc/Fc)	-	-
growth vs. ration slope (Mgr)	0.35[6]	0.02[6]	-0.547
growth vs. activity slope (Mga)	1.75 (Mfa*Mrf*Mgr)	-	-
initial weight	1 gram[8]	0.1[8]	1.00
control prey drift	1.0[4]	0.05[11]	0.116
AChE impact time-to-effect ($t_{1/2}$)	0.5 day[9]	n/a	0.005
AChE time-to-recovery ($t_{1/2}$)	30 days[10]	n/a	-0.0001
prey floor	0.20[11]	n/a	0.178
prey recovery rate	0.01[12]	n/a	0.323
somatic growth rate (Gc)	1.3[13]	0.06[6]	2.531

Table A1-4. Matrix transition element (standard deviation) and sensitivity (S) and elasticity (E) values for each model species. These control values are listed by the transition element taken from the life-history graphs as depicted in Figure A1-1 and the literature data described in the method text. Blank cells indicate elements that are not in the transition matrix for a particular species. The influence of each matrix element on λ was assessed by calculating the sensitivity (S) and elasticity (E) values for A. The sensitivity of matrix element a_{ij} equals the rate of change in λ with respect to the transition element, defined by $\delta\lambda / \delta a$. The elasticity of transition element a_{ij} is defined as the proportional change in λ relative to the proportional change in a_{ij}, and equals (a_{ij}/λ) times the sensitivity of a_{ij}. Elasticity values allow comparison of the influence of individual transition elements and comparison across matrices.

Transition Element	Chinook Stream-type			Chinook Ocean-type			Coho			Sockeye

Table A1-8. Acute mortality model output for ocean-type Chinook exposed to chlorpyrifos. The percent change in population growth rate (lambda), the population growth rate mean values (lambda mean), and the variability (standard deviations) are shown, along with the mean first year survival rate (S1). The toxicity values were LC_{50}=1.44, slope 3.6. The percent of the population exposed was also varied (left column). Bold indicates a percent change in population growth rage of greater than 1 standard deviation from control values (second column).

Table A1-12. Acute mortality model output for ocean-type Chinook exposed to diazinon. The percent change in population growth rate (lambda), the population growth rate mean values (lambda mean), and the variability (standard deviations) are shown, along with the mean first year survival rate (S1). The toxicity values were LC_{50}=237.9, slope 3.6. The percent of the population exposed was also varied (left column). Bold indicates a percent change in population growth rage of greater than 1 standard deviation from control values (second column).

Table A1-19. Acute mortality model output for coho exposed to malathion. The percent change in population growth rate (lambda), the population growth rate mean values (lambda mean), and the variability (standard deviations) are shown, along with the mean first year survival rate (S1). The toxicity values were LC_{50}=19.4, slope 3.6. The percent of the population exposed was also varied (left column). Bold indicates a percent change in population growth rage of greater than 1 standard deviation from control values (second column).

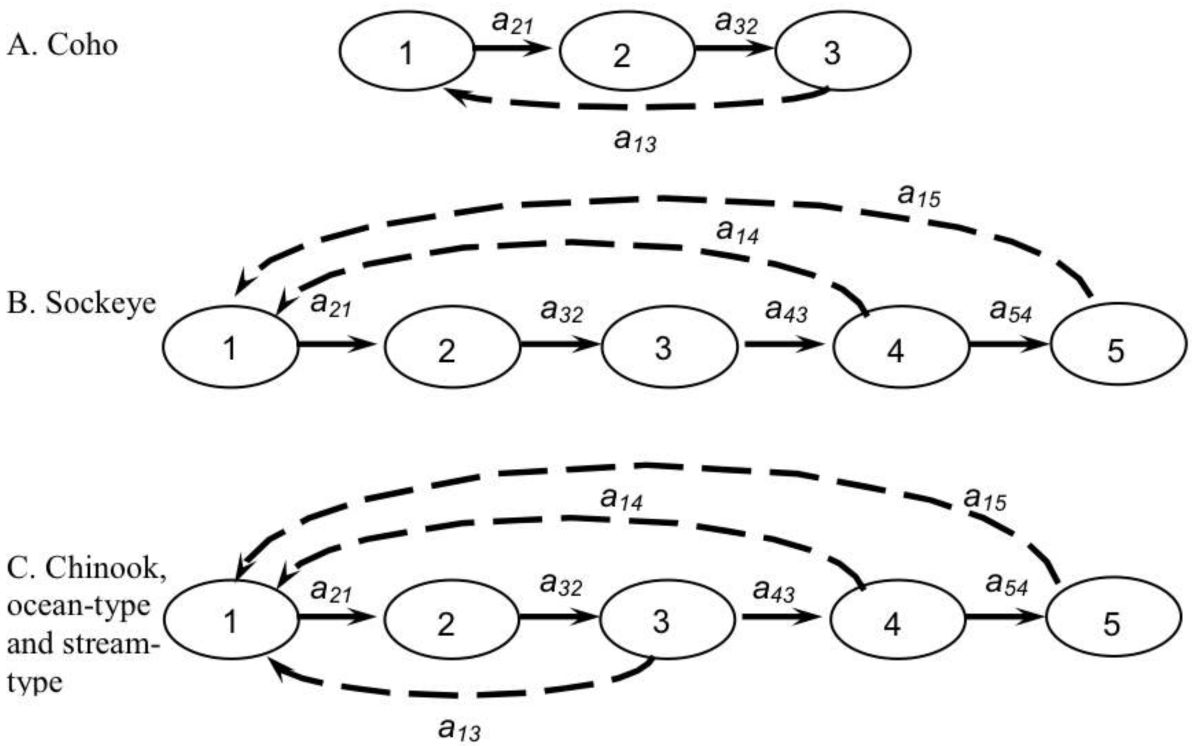
Figure A1-1: Life-History Graphs and Transition Matrix for coho (A), sockeye (B) and Chinook (C) salmon. The life-history graph for a population labeled by age, with each transition element labeled according to the matrix position, a_{ij}, i row and j column. Dashed lines represent reproductive contribution and solid lines represent survival transitions. D) The transition matrix for the life-history graph depicted in C.



D. Transition Matrix

$$A=\begin{bmatrix} 0 & 0 & R3=a_{13} & R4=a_{14} & R5=a_{15} \\ S1=a_{21} & 0 & 0 & 0 & 0 \\ 0 & S2=a_{32} & 0 & 0 & 0 \\ 0 & 0 & S3=a_{43} & 0 & 0 \\ 0 & 0 & 0 & S4=a_{54} & 0 \end{bmatrix}$$

Figure A1-2: Relationships used to link anticholinesterase exposure to the organism's ability to acquire food (potential ration). See text for details. Relationships in B, C, and D utilize empirical data. Closed circles represent control conditions. Open circles represent the exposed (inhibited) condition. A) Representation of a constant level of anticholinesterase pesticide exposure (either a single compound or mixtures). B) Sigmoidal relationship between exposure concentration and steady-state acetylcholinesterase (AChE) activity showing a dose-dependent reduction defined by control activity (horizontal line, Ac), sigmoidal (i.e. hille) slope (AChE slope), and the concentration producing 50% inhibition (vertical line, EC50). C) Timecourse of acetylcholinesterase inhibition based on modeling the time-to-effect and time-to-recovery as single exponential curves with different time-constants. At the start of the exposure AChE activity will be at control and then decline toward the inhibited activity (Ai) based on Panel B. D) Linear model relating acetylcholinesterase activity to feeding behavior using a line that passes through the feeding (Fc) and activity (Ac) control conditions with a slope of Mfa. E) The relationship between feeding behavior and the potential ratio an organism could acquire (if not food limited) used a line passing through the control conditions (Fc as in Panel D and the control ration, Rc) and through the origin producing a slope (Mrf) equal to Rc/Fc. F) Timecourse for effect of exposure to anticholinesterase on potential ration produced by combining C & E.

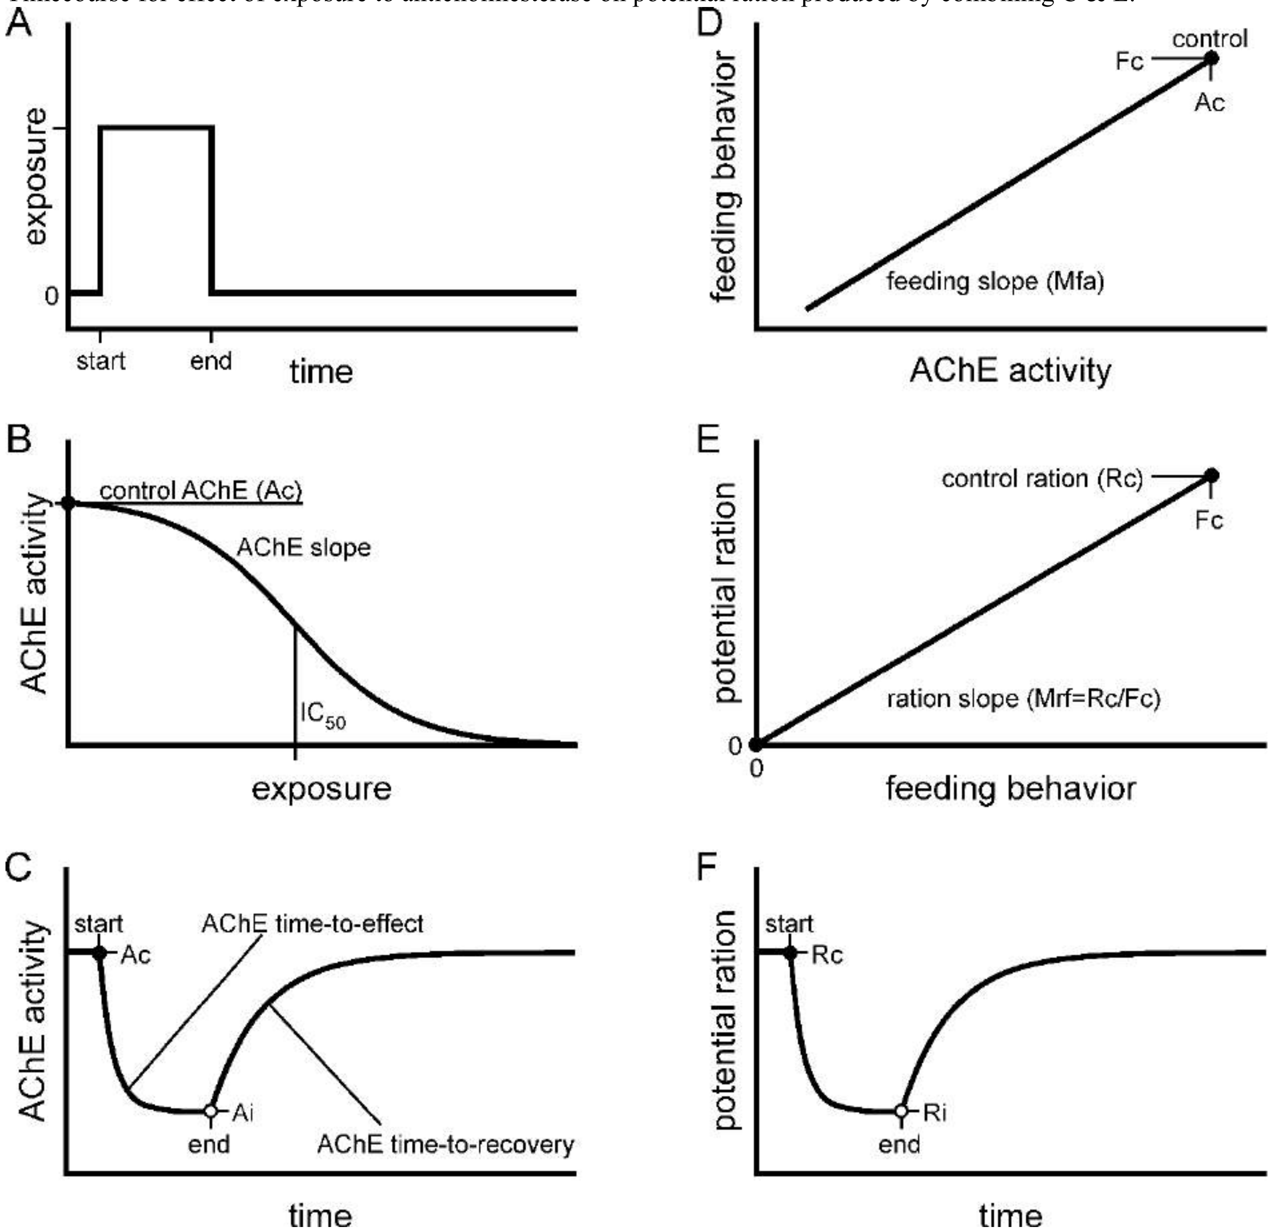


Figure A1-3: Relationships used to link anticholinesterase exposure to the availability of prey. See text for details. Relationships in B and C utilize empirical data. Closed circles represent control conditions. Open circles represent the exposed (inhibited) condition. A) Representation of a constant level of anticholinesterase pesticide exposure (either single compound or mixtures). B) Sigmoidal relationship between exposure concentration and relative prey abundance showing a dose-dependent reduction defined by control abundance (horizontal line at 1, Pc), sigmoid (i.e. hille) slope (prey slope), the concentration producing a 50% reduction in prey (vertical line, EC_{50}), and a minimum abundance always present (horizontal line denoted as floor, Pf). C) Timecourse of prey abundance including a 1-day spike in prey drift relative to the available prey and the level of toxicity followed by a drop to the level of impact or the floor whichever is greater. During extended exposures at low toxicity recovery can begin at the constant prey influx rate multiplied by the current level of toxicity. After exposure recovery to control prey drift is at the constant rate of influx from upstream habitats.

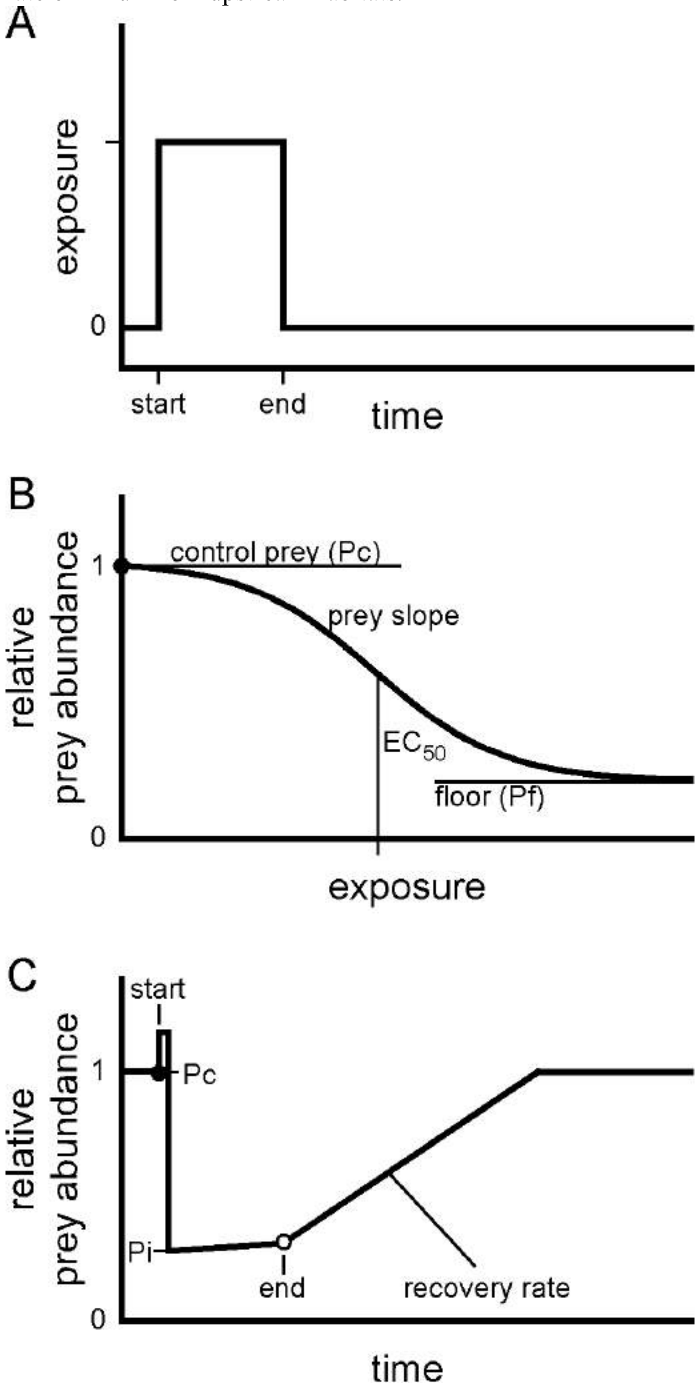

Figure A1-4: Relationships used to link anticholinesterase exposure to growth rate relating to long-term weight gain of each fish. See text for details. Relationships in A, B, and C utilize empirical data. Closed circles represent control conditions. Open circles (e.g. Ai) represent the exposed (inhibited) condition. A&B) Relationships describing the Timecourse of the effects of anticholinesterase exposure on the organisms ability to capture food (Panel A, potential ration) and the availability of food to capture (Panel B, relative prey abundance). The figures are the same as those in Figures A1-2F and 3C, respectively. For a given exposure concentration and time, multiplying potential ration by relative prey abundance yields the final ration acquired by the organism. C) A linear model was used to relate final ration to growth rate using a line passing through the control conditions and through the maintenance condition with a slope denoted by Mgr. D) Timecourse for effect of exposure to anticholinesterase on growth rate produced by combining A, B, & C.

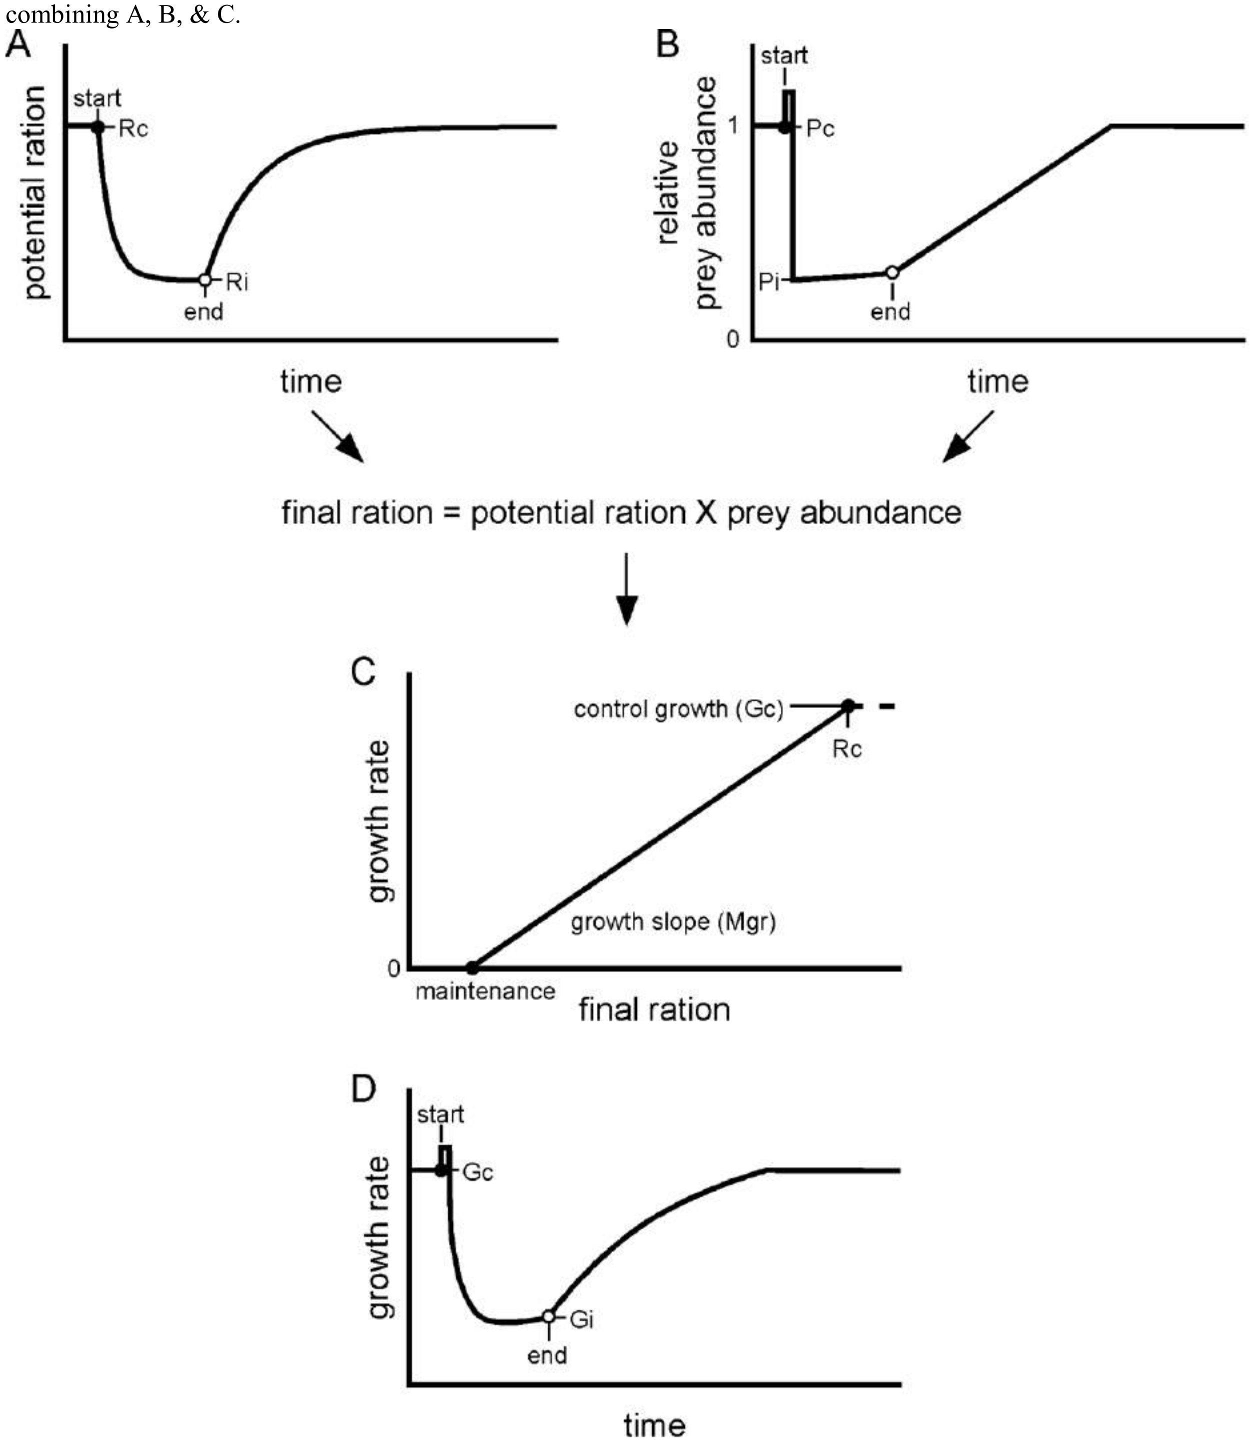

Figure A1-5: Somatic growth model output for chlorpyrifos, malathion and diazinon. Scenario used to generate output was a single, 4-d exposure beginning on day 30 of the somatic growth period with 100% of the population exposed. Lines indicate mean percent change in lambda and caps show one standard deviation.

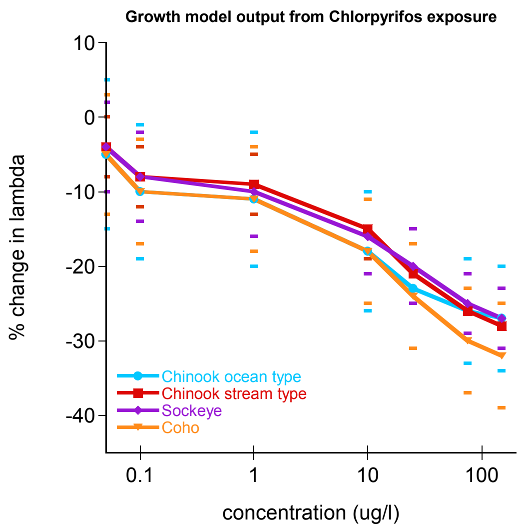

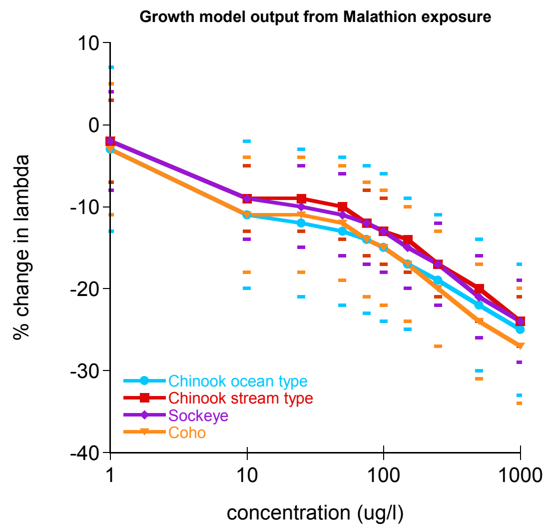

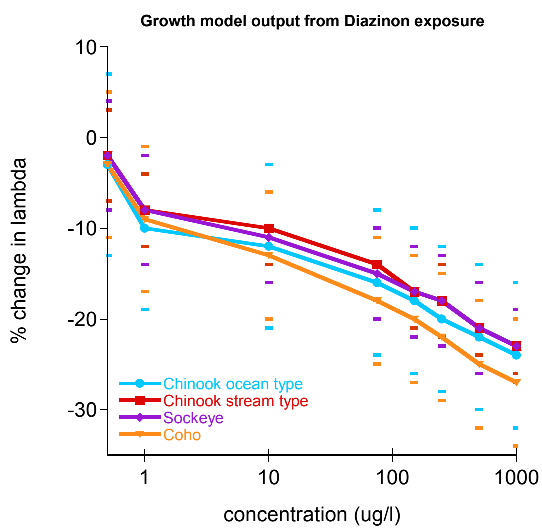

Figure A1-6: Percent change in population growth rate (lambda) for salmon populations exposed to malathion at concentrations across the range of EECs which resulted in acute mortality. Each line represents the mean percent change in lambda for different percentages of the population exposed (100%, 75%, 50%, and 25%) and caps show one standard deviation.

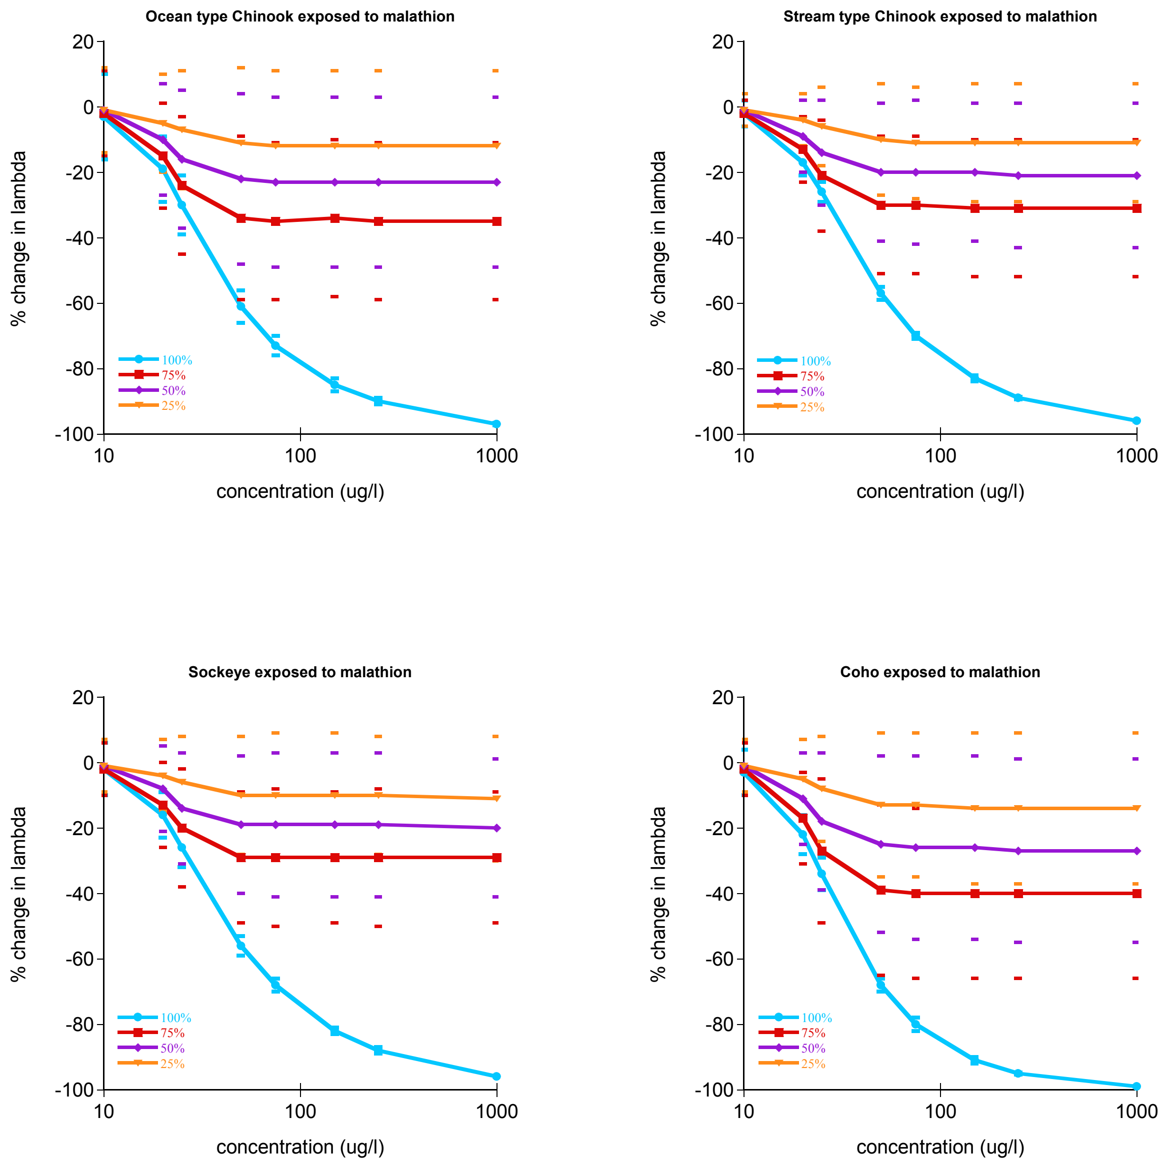

Figure A1-7: Percent change in population growth rate (lambda) for salmon populations exposed to chlorpyrifos at concentrations across the range of EECs which resulted in acute mortality. Each line represents the mean percent change in lambda for different percentages of the population exposed (100%, 75%, 50%, and 25%) and caps show one standard deviation.

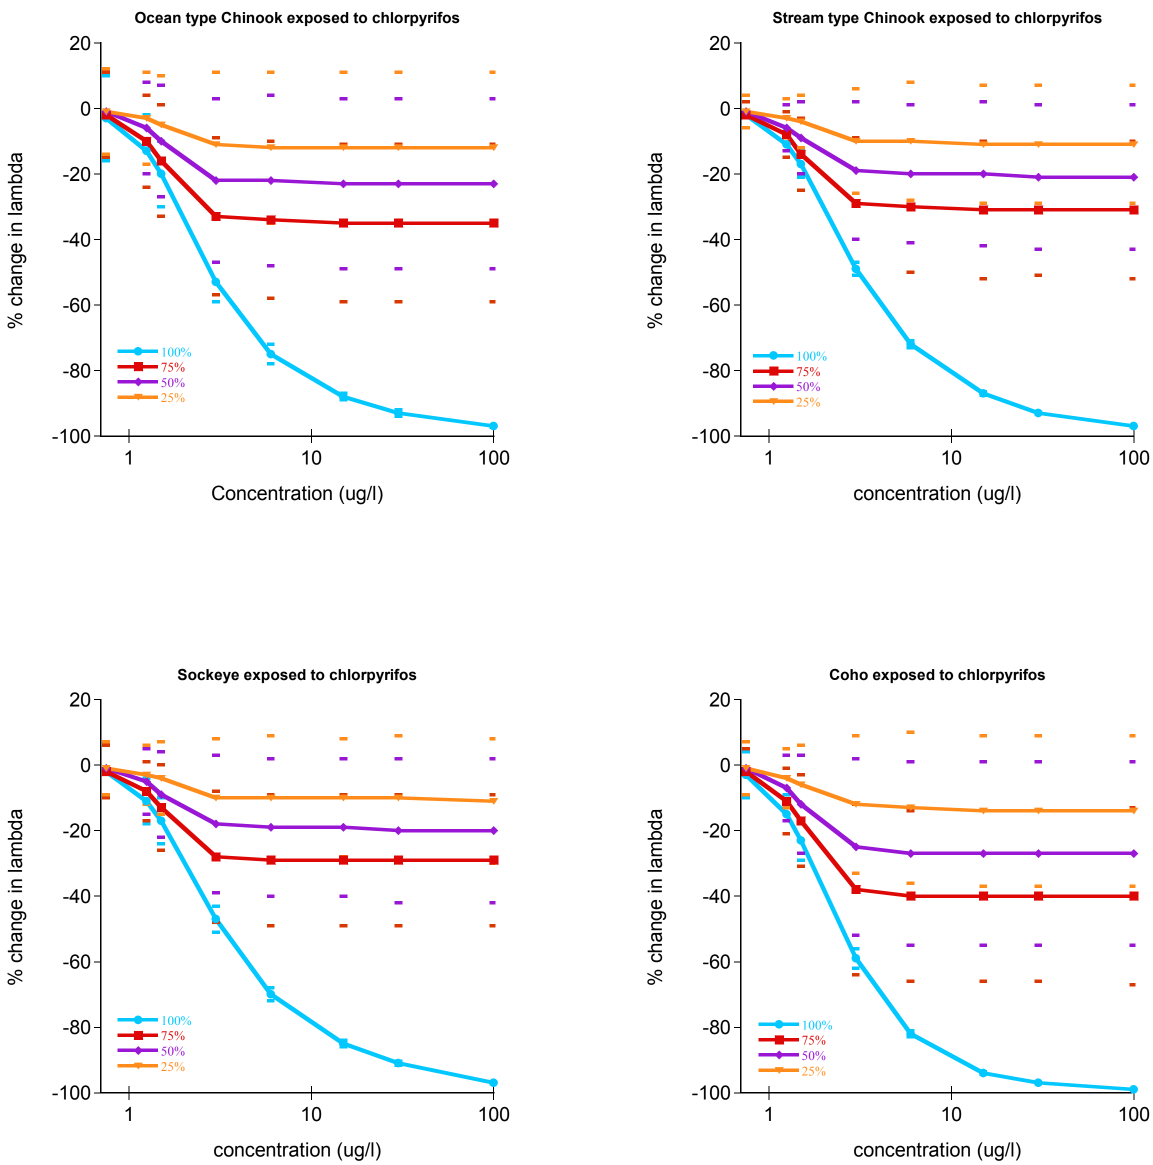

Figure A1-8: Percent change in population growth rate (lambda) for salmon populations exposed to diazinon at concentrations across the range of EECs which resulted in acute mortality. Each line represents the mean percent change in lambda for different percentages of the population exposed (100%, 75%, 50%, and 25%) and caps show one standard deviation.

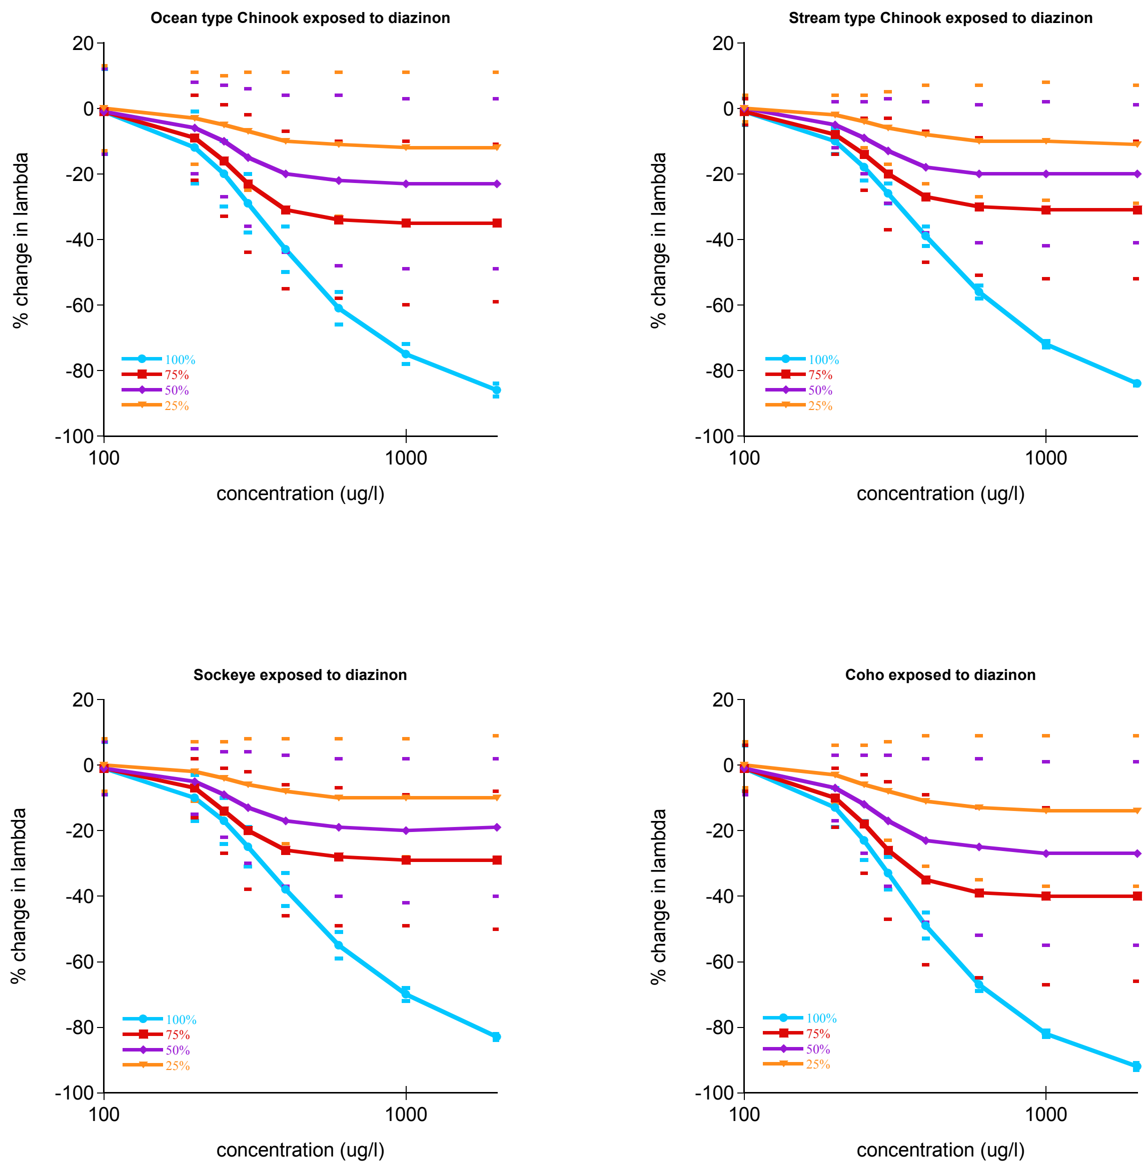

C. APPENDIX: PHYSICAL OR BIOLOGICAL FEATURES ESSENTIAL FOR THE CONSERVATION OF THE SPECIES

Table 1. Physical or biological features essential for the conservation of the species for NMFS ESA listed species under consultation (pacific salmonids not included in this table).

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Black Abalone *Haliotis cracherodii*	76 FR66806 10/27/2011	• Rocky substrate: Rocky benches, crevices, large boulders • Food resources: Bacterial and diatom films, algae • Juvenile settlement habitat: Rocky habitat with coralline algae and/or crevices, cryptic biogenic structures • Suitable water quality • Suitable nearshore circulation patterns
White Abalone *Haliotis sorenseni*	66 FR29046 05/29/2001	NO DESIGNATED CRITICAL HABITAT. A designation was deemed not prudent because it was expected to increase risk of poaching
Elkhorn Coral *Acropora palmate* & Staghorn Coral *Acropora cervicornis*	73 FR 72210 11/26/2008	Substrate of suitable quality and availability to support successful larval settlement and recruitment, and reattachment and recruitment of fragments
Johnson's seagrass *Halophila johnsonii*	65 FR 17768 04/05/2000	• Adequate water quality, salinity levels, water transparency • Stable, unconsolidated sediments free from disturbance
Green Turtle Chelonia mydas: Florida & Mexico Pacific coast breeding colonies; all other areas	63 FR 46693 09/02/1998	Activities requiring special management considerations include: • Vessel traffic • Coastal construction • Point and non-point source pollution • Fishing activities • Dredge and fill activities • Habitat restoration
Hawksbill Turtle	63 FR 46693	

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Eretmochelys imbricata	09/02/1998	
Leatherback Turtle *Dermochelys coriacea*	44 FR 17710 03/23/1979 77 FR 4170 01/26/2012	Activities identified as modifying CH include: recreational boating • swimming, • sandmining (see 77 FR 32909 for the 6/4/2012 determination on Sierra Club's petition to revise the CH) • Occurrence of prey species, primarily Scyphomedusae of the order Semaeostomeae (*Chrysaora, Aurelia, Phacellophora, and Cyanea*) of sufficient condition, distribution, diversity, and abundance to support individual as well as population growth, reproduction, and development • Migratory pathway conditions to allow for safe and timely passage and access to/from/within high use foraging areas
Loggerhead Turtle Caretta caretta: Northwest Atlantic Ocean Loggerhead Turtle *Caretta caretta*: Northwest Atlantic Ocean (continued)	79 FR 39855 07/10/2014 79 FR 39855 07/10/2014	**Nearshore Reproductive Habitat** • Nearshore waters directly off the highest density nesting beaches and their adjacent beaches as identified in 50 CFR 17.95(c) to 1.6 km (1 mile) offshore; • Waters sufficiently free of obstructions or artificial lighting to allow transit through the surf zone and outward toward open water. • Waters with minimal manmade structures that could promote predators (i.e., nearshore predator concentration caused by submerged and emergent offshore structures), disrupt wave patterns necessary for orientation, and/or create excessive longshore currents. **Winter Habitat** • Water temperatures above 10° C from • November through April; • Continental shelf waters in proximity to the western boundary of the Gulf Stream; and • Water depths between 20 and 100 m.

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Loggerhead Turtle *Caretta caretta*: Northwest		**Breeding Habitat** • High densities of reproductive male and female loggerheads; • Proximity to primary Florida migratory corridor; and • Proximity to Florida nesting grounds. **Migratory Habitat** • Constricted continental shelf area relative to nearby continental shelf waters that concentrate migratory pathways; and • Passage conditions to allow for migration to and from nesting, breeding, and/or foraging areas. **Sargassum Habitat** • Convergence zones, surface-water downwelling areas, the margins of major boundary currents (Gulf Stream), and other locations where there are concentrated components of the Sargassum community in water temperatures suitable for the optimal growth of Sargassum and inhabitance of loggerheads; • Sargassum in concentrations that support adequate prey abundance and cover; • Available prey and other material associated with Sargassum habitat including, but not limited to, plants and cyanobacteria and animals native to the Sargassum community such as hydroids and copepods; and • Sufficient water depth and proximity to available currents to ensure offshore transport (out of the surf zone), and foraging and cover requirements by Sargassum for post-hatchling loggerheads, i.e., >10 m depth.

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Atlantic Ocean (continued)		
Killer Whale Orcinus orca: Southern Resident	71 FR 69054 11/29/2006	• Water quality to support growth and development; • Prey species of sufficient quantity, quality and availability to support individual growth, reproduction and development, as well as overall population growth; and • Passage conditions to allow for migration, resting, and foraging.
Hawaiian Monk Seal *Neomonachus schauinslandi*	51 FR 16047 04/30/1986 53 FR 18988 05/26/1988 extended CH from 10 to 20 fathoms deep around NWHI 80 FR 50925 8/21/2015	• Pupping and major hauling beaches including the vegetation immediately backing the beaches (coral sand beaches and lava benches). • Shallow protected water adjacent to the above (tide pools, inner reef waters, shoal areas, and near shore shallows). • Deeper inner reef areas and lagoon waters. • Other waters surrounding the NWHI to at least 80 fathoms. • Banks and shoals without emergent lands and pelagic waters. • Terrestrial areas and adjacent shallow, sheltered aquatic areas with characteristics preferred by monk seals for pupping and nursing • Marine areas from 0 to 200 m in depth that support adequate prey quality and quantity for juvenile and adult monk seal foraging • Significant areas used by monk seals for hauling out, resting, or molting
Stellar Sea Lion *Eumetopias jubatus:* (Eastern DPS delisted, but CH still in effect; see 78 FR 66139)	58 FR 45269 8/27/1993	**Terrestrial, air, and aquatic areas that support:** • Reproduction • Foraging • Rest • Refuge

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Atlantic Salmon Salmo salar: Gulf of Maine	74 FR 29300 6/19/2009	**Spawning and Rearing** • Deep, oxygenated pools and cover (e.g., boulders, woody debris, vegetation, etc.), near freshwater spawning sites, necessary to support adult migrants during summer while they await spawning in the fall. • Freshwater spawning sites that contain clean, permeable gravel and cobble substrate with oxygenated water and cool water temperatures to support spawning activity, egg incubation, and larval development. • Freshwater spawning and rearing sites with clean, permeable gravel and cobble substrate with oxygenated water and cool water temperatures to support emergence, territorial development and feeding activities of Atlantic salmon fry. • Freshwater rearing sites with space to accommodate growth and survival of Atlantic parr. • Freshwater rearing sites with a combination of river, stream, and lake habitats that accommodate parr's ability to occupy many niches and maximize parr production. **Migration** • Freshwater and estuary migratory sites free from physical and biological barriers that delay or prevent access of adult seeking spawning grounds needed to support recovered populations. • Freshwater and estuary migration sites with pool, lake, and instream habitat that provide cool, oxygenated water and cover items (e.g., boulders, woody debris, and vegetation) to serve as temporary holding and resting areas during upstream migration of adult Atlantic salmon. • Freshwater and estuary migration sites with abundant, diverse native fish communities to serve as a protective buffer against predation. • Freshwater and estuary migration sites free from physical and biological barriers that delay or

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Atlantic Salmon *Salmo salar* (continued)	74 FR 29300 6/19/2009	prevent emigration of smolts to the marine environment. • Freshwater and estuary migration sites with sufficiently cool water temperatures and water flows that coincide with diurnal cues to stimulate smolt migration.
Smalltooth Sawfish Pristis pectinata	74 FR 45353 09/02/2009	**Juvenile Nursery Habitat** • Red mangroves, and • Adjacent shallow euryhaline habitats and • the nursery area functions they provide to facilitate recruitment of juveniles into the adult population.
Gulf Sturgeon Acipenser oxyrinchus desotoi	68 FR 13370 03/19/2003	• Abundant food items, such as detritus, aquatic insects, worms, and/or molluscs, within riverine habitats for larval and juvenile life stages; and abundant prey items, such as amphipods, lancelets, polychaetes, gastropods, ghost shrimp, isopods, molluscs and/or crustaceans, within estuarine and marine habitats and substrates for subadult and adult life stages. • Riverine spawning sites with substrates suitable for egg deposition and development, such as limestone outcrops and cut limestone banks, bedrock, large gravel or cobble beds, marl, soapstone, or hard clay; • Riverine aggregation areas, also referred to as resting, holding, and staging areas, used by adult, subadult, and/or juveniles, generally, but not always, located in holes below normal riverbed depths, believed necessary for minimizing energy expenditures during fresh water residency and possibly for osmoregulatory functions; • A flow regime (i.e., the magnitude, frequency, duration, seasonality, and rate-of-change of fresh water discharge over time) necessary for normal behavior, growth, and survival of all life stages in the riverine environment, including migration, breeding site selection, courtship, egg fertilization, resting, and staging, and for

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Gulf Sturgeon Acipenser oxyrinchus desotoi (continued)	68 FR 13370 03/19/2003	maintaining spawning sites in suitable condition for egg attachment, egg sheltering, resting, and larval staging; • Water quality, including temperature, salinity, pH, hardness, turbidity, oxygen content, and other chemical characteristics, necessary for normal behavior, growth, and viability of all life stages; • Sediment quality, including texture and other chemical characteristics, necessary for normal behavior, growth, and viability of all life stages; and • Safe and unobstructed migratory pathways necessary for passage within and between riverine, estuarine, and marine habitats (e.g., an unobstructed river or a dammed river that still allows for passage).
Green Sturgeon Acipenser medirostris: *Southern*	74 FR 52300 10/9/2009	**Freshwater areas** • *Food resources.* Abundant prey items for larval, juvenile, subadult, and adult life stages. • Substrate type or size (i.e., structural features of substrates) • Water flow. A flow regime (i.e., the magnitude, frequency, duration, seasonality, and rate-of-change of fresh water discharge over time) necessary for normal behavior, growth, and survival of all life stages. • Water quality. Water quality, including temperature, salinity, oxygen content, and other chemical characteristics, necessary for normal behavior, growth, and viability of all life stages. • Migratory corridor. A migratory pathway necessary for the safe and timely passage of Southern DPS fish within riverine habitats and between riverine and estuarine habitats (e.g., an unobstructed river or dammed river that still allows for safe and timely passage). • Water depth. Deep (≥5 m) holding pools for both upstream and downstream holding of adult or subadult fish, with adequate water quality and flow to maintain the physiological needs of the holding adult or subadult fish.

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Green Sturgeon Acipenser medirostris *(continued)*	74 FR 52300 10/9/2009	• Sediment quality. Sediment quality (i.e., chemical characteristics) necessary for normal behavior, growth, and viability of all life stages. **Estuarine areas** • Food resources. Abundant prey items within estuarine habitats and substrates for juvenile, subadult, and adult life stages. • Water flow. Within bays and estuaries adjacent to the Sacramento River (*i.e.,* the Sacramento-San Joaquin Delta and the Suisun, San Pablo, and San Francisco bays), sufficient flow into the bay and estuary to allow adults to successfully orient to the incoming flow and migrate upstream to spawning grounds. • *Water quality.* Water quality, including temperature, salinity, oxygen content, and other chemical characteristics, necessary for normal behavior, growth, and viability of all life stages. • Migratory corridor. A migratory pathway necessary for the safe and timely passage of Southern DPS fish within estuarine habitats and between estuarine and riverine or marine habitats. • Water depth. A diversity of depths necessary for shelter, foraging, and migration of juvenile, subadult, and adult life stages. • Sediment quality. Sediment quality (i.e., chemical characteristics) necessary for normal behavior, growth, and viability of all life stages. This includes sediments free of elevated levels of contaminants **Coastal Marine Areas** • Migratory corridor. A migratory pathway necessary for the safe and timely passage of Southern DPS fish within marine and between estuarine and marine habitats. • Water quality. Coastal marine waters with adequate dissolved oxygen levels and acceptably low levels of contaminants (e.g., pesticides, PAHs, heavy metals that may disrupt the normal

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Green Sturgeon Acipenser medirostris *(continued)*	74 FR 52300 10/9/2009	behavior, growth, and viability of subadult and adult green sturgeon). • Food resources. Abundant prey items for subadults and adults, which may include benthic invertebrates and fish.
Atlantic sturgeon *Acipenser oxyrinchus oxyrinchus* Gulf of Maine DPS	81 FR 35701 6/3/2016 PROPOSED	• Hard bottom substrate (*e.g.,* rock, cobble, gravel, limestone, boulder, etc.) in low salinity waters (*i.e.,* 0.0 to 0.5 parts per thousand range) for settlement of fertilized eggs, refuge, growth, and development of early life stages • Aquatic habitat with a gradual downstream salinity gradient of 0.5 to 30 parts per thousand and soft substrate (*e.g.,* sand, mud) downstream of spawning sites for juvenile foraging and physiological development • Water of appropriate depth and absent physical barriers to passage (*e.g.,* locks, dams, reservoirs, gear, etc.) between the river mouth and spawning sites necessary to support: (1) Unimpeded movement of adults to and from spawning sites; (2) seasonal and physiologically dependent movement of juvenile Atlantic sturgeon to appropriate salinity zones within the river estuary; and (3) staging, resting, or holding of subadults or spawning condition adults. Water depths in main river channels must also be deep enough (*e.g.,* ≥1.2 m) to ensure continuous flow in the main channel at all times when any sturgeon life stage would be in the river • Water, especially in the bottom meter of the water column, with the temperature, salinity,
Atlantic sturgeon *Acipenser oxyrinchus oxyrinchus* New York Bight DPS	81 FR 35701 6/3/2016 PROPOSED	
Atlantic sturgeon *Acipenser oxyrinchus oxyrinchus*	81 FR 35701 6/3/2016 PROPOSED	

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
Chesapeake Bay DPS		and oxygen values that, combined, support: (1) Spawning; (2) annual and interannual adult, subadult, larval, and juvenile survival; and (3) larval, juvenile, and subadult growth, development, and recruitment (*e.g.,* 13 °C to 26 °C for spawning habitat and no more than 30° C for juvenile rearing habitat, and 6 mg/L dissolved oxygen for juvenile rearing habitat)
Atlantic sturgeon *Acipenser oxyrinchus oxyrinchus* Carolina DPS	81 FR 36077 6/3/2016 PROPOSED	• Suitable hard bottom substrate (*e.g.,* rock, cobble, gravel, limestone, boulder, etc.) in low salinity waters (*i.e.,* 0.0-0.5 ppt range) for settlement of fertilized eggs and refuge, growth, and development of early life stages • Transitional salinity zones inclusive of waters with a gradual downstream gradient of 0.5-30 ppt and soft substrate (*e.g.,* sand, mud) downstream of spawning sites for juvenile foraging and physiological development • Water of appropriate depth and absent physical barriers to passage (*e.g.,* locks, dams, reservoirs, gear, etc.) between the river mouth and spawning sites necessary to support: (1) Unimpeded movement of adults to and from spawning sites; (2) seasonal and physiologically dependent movement of juvenile Atlantic sturgeon to appropriate salinity zones within the river estuary; and (3) staging, resting, or holding of subadults and spawning condition adults. Water depths in main river channels must be deep enough to ensure continuous flow in the main channel at all times when any sturgeon life stage would be in the river. Water depths of at least 1.2 m are generally deep enough to facilitate effective adult migration and spawning behavior • Water quality conditions, especially in the bottom meter of the water column, with temperature and oxygen values that support: (1) Spawning; (2) annual and inter-annual adult, subadult, larval, and juvenile survival; and (3) larval, juvenile, and subadult growth, development, and recruitment. Appropriate temperature and oxygen values will vary
Atlantic sturgeon *Acipenser oxyrinchus oxyrinchus* South Atlantic DPS	81 FR 36077 6/3/2016 PROPOSED	

Species	FR Notice /Date	Physical or Biological Features Essential for the Conservation of the Species
		interdependently, and depending on salinity in a particular habitat. For example, 6.0 mg/L D.O. for juvenile rearing habitat is considered optimal, whereas D.O. less than 5.0 mg/L for longer than 30 days is considered suboptimal when water temperature is greater than 25 °C. In temperatures greater than 26 °C, D.O. greater than 4.3 mg/L is needed to protect survival and growth. Temperatures of 13 °C to 26 °C for spawning habitat are considered optimal
Eulachon Thaleichthys pacificus*:* *Southern*	76 FR 65323 10/20/2011	• Freshwater spawning and incubation sites with water flow, quality and temperature conditions and substrate supporting spawning and incubation, and with migratory access for adults and juveniles. ° Flow: A flow regime (i.e., the magnitude, frequency, duration, seasonality, and rate-of-change of freshwater discharge over time) that supports spawning, and survival of all life stages. ° Water Quality: Water quality suitable for spawning and viability of all eulachon life stages. Sublethal concentrations of contaminants affect the survival of aquatic species by increasing stress, predisposing organisms to disease, delaying development, and disrupting physiological processes, including reproduction. ° Water Temperature: Suitable water temperatures, within natural ranges, in eulachon spawning reaches. ° Substrate: Spawning substrates for eulachon egg deposition and development. • Freshwater and estuarine migration corridors associated with spawning and incubation sites that are free of obstruction and with water flow, quality and temperature conditions supporting larval and adult mobility, and with abundant prey items supporting larval feeding after the yolk sac is depleted. ° Migratory Corridor: Safe and unobstructed migratory pathways for eulachon adults to

Atlantic sturgeon	South Atlantic	No
Gulf Sturgeon	NA	No
Smalltooth sawfish	U.S. Portion of Range	Yes

Toxicological Data

The toxicological data used for each of the 30 species assessed are presented in ***Table 2***. Direct mortality was assessed for each compound with comparison to the HC05 LC50 with a standard dose-response slope of 4.5. Species sensitivity distributions (SSD) were generated and described by EPA in the Biological Evaluation's effects characterization (chapter 2). The LC50s used were those associated with the "all fish", "all aquatic vertebrate" and "fish" SSDs for chlorpyrifos, diazinon, and malathion, respectively (BE appendix 2-6).

In addition to assessing direct mortality to listed species, the MagTool was used to generate mortality estimates for prey. Prey mortality was assessed for each compound with comparison to the HC10 LC50, again with a standard dose-response slope of 4.5. Invertebrate "pooled results" SSDs were used for all three compounds (BE appendix 2-8).

Table 2. Toxicological endpoints used to parameterize the MagTool. Values taken directly from EPA's BEs appendix 2-6 and 2-8.

Compound	Endpoint	LC50 value (ppb)	Slope
Chlorpyrifos	Direct mortality - all fish HC05	1.44	4.5
	Indirect (prey) - all fish HC10	2.78	4.5
	Indirect (prey) - Invert HC10	0.072	4.5
Diazinon	Direct mortality – all aquatic vertebrate HC05	237.9	4.5
	Indirect (prey) - all fish HC10	433.2	4.5
	Indirect (prey) - Invert HC10	0.85	4.5
Malathion	Direct – fish HC05	19.4	4.5
	Indirect (prey) - all fish HC10	30.5	4.5
	Indirect (prey) - Invert HC10	1.7	4.5

Time-weighted Average

Toxicological data were compared to EECs representing 1-day and 4-day time-weighted averages for both direct mortality and mortality to prey, as provided in the BEs.

Variability Reported

Probabilistic output is reported reflecting variability in EECs derived by incorporating geographically-specific estimates that account for two sources of variability: (1) the occurrence of pesticide use sites within the species range (six year data set), and (2) daily precipitation (30 year data set). In Appendix A (MagTool Results for Listed Species) NMFS has reported mortality estimates associated with the 5th, 50th, and 95th percentile probabilities for each of the appropriate bins (modeled aquatic habitats).

Adjustment Factors

The MagTool allows for adjustment factors to be applied by use site (e.g. corn, wheat) or by HUC-12 (sub-watershed region). These adjustment factors can be used to either modify the percent overlap or the magnitude of EECs associated with each of the use sites. The adjustment factors also allow the user to customize the distribution of species throughout their range (by HUC-12). NMFS utilized adjustment factors in order to exclude wide area use and mosquito adulticide, but did not use any other adjustment factors in generating estimates for the 30 anadromous species assessed.

Wide Area Use & Mosquito Adulticide

The MagTool relies on spatial data (GIS use-layers) to determine the extent of overlap between the species range and each of the use sites (e.g. corn, wheat). In some cases, data layers for use sites overlap. Use-layer overlap is often appropriate (multiple uses authorized for the same location), however, because the MagTool equates percent overlap with percent exposed, the overlapping layers can lead to difficulty in interpretation. This MagTool assumption can result in either the overestimation or underestimation of risk (see Chapter 11.6.4).

Chlorpyrifos is authorized for two uses which have no restriction on location: wide area use and mosquito adulticide; malathion is authorized for wide area use. NMFS excluded these uses from the MagTool calculations to help simplify the interpretation of the results. While excluded from the MagTool, these uses have been retained in the R-plots and incorporated into the effects analysis. See Appendix D (MagTool Description) for more information on the MagTool and redundancy in spatial overlap between use layers.

MagTool - Conceptual Model Design (Aquatic)

The Magnitude of Effect tool (MagTool) is a provisional model[1] created by the USEPA to assist in the determination of the magnitude of the effect of potential pesticide use to a listed species on a population scale. The MagTool uses the results generated in the Step 2 Biological Evaluation (BE) analysis to carry forward into the Step 3 population-level analysis for multiple lines of evidence, including mortality, growth, reproductive, behavioral and sensory effects. Using dose response relationships, the MagTool predicts the magnitude of mortality for exposed individuals within a population. These individual mortality predictions are combined with information on the percent overlap of specific use sites with the species range and/or critical habitat to predict the percent mortality predicted in the population, using the percent overlap of specified pesticide use sites with the species range and/or critical habitat as a surrogate for the percent of population exposed. Adjustments can be made to the percent of population exposed depending on species and use characteristics, as well as limiting the specific use sites included in the analysis. Potential population impacts due to sublethal effects are made based on estimated exposure concentrations

[1] As a provisional model, the MagTool is still undergoing internal QA/QC at the USEPA.

(EECs) exceeding sublethal toxicity input parameters and the percent of population exposed to these EECs.

The MagTool consists of two separate software tools; one for terrestrial species and a second for aquatic species. Several principles of their model design that are shared are described below. Additional information specific to the Aquatic MagTool is also described. Details specific to the Terrestrial MagTool are not described.

Geospatial Overlap Analysis

Methods for identifying potential pesticide use sites using USDA National Agriculture Statistic Service (NASS) Cropland data layer (CDL) for agricultural uses and other data sources for non-agricultural uses are outlined in the Problem Formulation and Attachment 1-3 (Method for Establishing the Use Site Footprints of the Biological Evaluations) of the BEs (https://www.epa.gov/endangered-species/biological-evaluation-chapters-chlorpyrifos-esa-assessment). Using this methodology, the intersection of the species geospatial range and/or critical habitat with relevant use sites for the pesticide is used to determine a "percent overlap". Major differences between the spatial analyses in the BEs as compared to the analysis used in the provisional MagTool model are discussed here.

One primary difference between the Step 2 and Step 3 overlap analysis is that the individual years of CDL data (2010-2015), summarized to the general agricultural classes, were used in Step 3 as opposed to the temporally aggregated general class layers which were utilized in Step 2 (non-agricultural layers stay the same from 2010 to 2015). This allows for the calculation of percent mortality and a distribution of anticipated effects by individual use footprint for each year. One exception for the MagTool is the calculation of spray drift impacts based on Euclidean distance (described below), which was still based on the aggregated use layers utilized in Step 2. Yearly overlap can only be created for use layers derived from data sources updated on a yearly time step; at this time this only applies to those layers generated from the USDA NASS CDL. The CDL is limited to the contiguous United States (lower 48), so the MagTool is only used for species with ranges in the lower 48. For this reason, results from the MagTool only represent the area of the species files found within the contiguous United States. The area of the species files found partially or completely outside the lower 48 cannot be fully analyzed using the MagTool. The results from the BE describing the overlap for the full range or critical habitat, based on the aggregated layers is available in the tool. Buffered and drift results are also based on the aggregated layers and the full range or critical habitat file.

Another addition in the MagTool geospatial analysis is the use of Hydrologic Unit Code areas at the 12-digit scale (HUC 12s) to spatially define aquatic species. Using the species locations files provided by the Services, all intersecting HUC 12s are identified and used as the master species location file. When instructed by the Services, the master file was not replaced with the HUC 12 intersection; this occurred typically for species with both terrestrial and aquatic phases or primarily marine species. When the master species file is not based on HUC 12s, the reported overlap from the BE may not match the HUC 12 overlap from the MagTool.

Finally, in order to predict species impacts due to off-site transport, the "Euclidean distance" is used to determine the proportion of the species range within each desired distance interval from a use site. The use site may be within the species range or outside the species range. Euclidean distance, or the shortest distance between two points, is defined in GIS modeling as the distance from center point of one pixel (e.g. location within the species range) center point of another pixel (e.g. the location of pesticide use in a raster map). These distances are projected off-site and are used to describe how overlap from spray drift intersects with a species range. At each incremental distance off site (set at 30 m), the % overlap with the species range is determined. The use of Euclidean distance in combination with predicted off-site EECs to predict off-site effects is discussed further in "Spray Drift Effects – Incorporating Euclidean distance overlap with EECs to predict mortality" section below. Examples of Euclidean distances are shown in Figure 1, below.

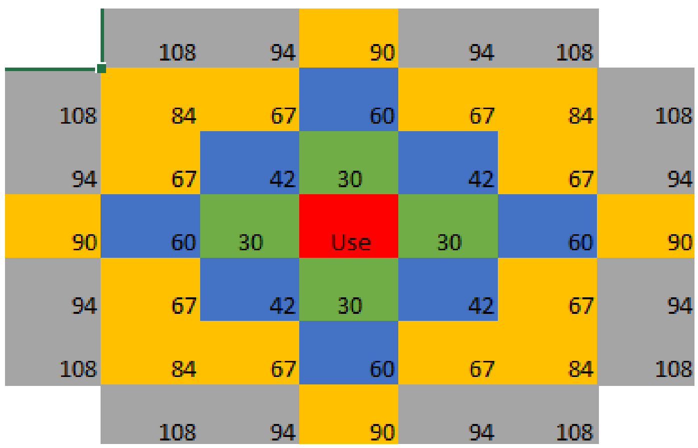

Figure 1. Euclidean distance off-site transport "rings" as determined for use in the MagTool.

Bulleted below are some additional points to consider in the interpretation of the overlap analysis in the MagTool.

- When predicting overall mortality in an exposed population, the tool provides predicted mortality from individual use layers as well as the mortality output of all of the individual use layers for each year combined. When summing the individual results, total overlap likely exceeds 100% when individual uses overlap one another. Without considering unmapped uses such as Mosquito Control, the total percent overlap cannot exceed the percent overlap of the action area. The extent to which individual use layers overlap one another nationally is provided in Attachment 1 and should be considered when interpreting results. Likewise, low overlap for an individual use may not indicate low overall spatial overlap of uses with the species range (*i.e.,* all uses should be considered).
- Given that all use layers are rasters comprised of square pixels, the overlap of the species and use site may include edge effects, potentially resulting in greater than 100% overlap.

The boundaries of the species range files are irregular and do not follow the straight lines and right angles of square. If you were to place a circle on top of a square with the diameter of the circle equal to the edge of the square pixel, the square will cover more area in the four corners. When running a raster analysis that is based on square pixels, the total area may exceed the area of a range that does not have right angle edges, resulting in greater than 100% overlap.

- Euclidean distances, as utilized in ArcGIS, calculate the distance based on the distance from the center point of a pixel in the use raster map to the center point of another pixel location, accounting for diagonal movement. Therefore, as shown in Figure 1 above, the distance for pixels not on a straight line to the use pixel, will actually be more than 30 m because it lies on a diagonal line. For the figure above, the green squares fall in the >0–30 m, the blue squares in the 31-60 m, the orange squares in the 61-90 m, etc. The use of a 30 m increment is based on the pixel size of the CDL use raster maps, but could be established at 20, 50, 100 or any other meter increment.
- Euclidean distance "rings" extend out from all use sites. If a ring from one use site encounters the ring from a different use site, the minimum distance to use is assigned as the distance value for that cell. The proportion of the species range found in each ring is represented by the % overlap at each distance interval, which for the purpose of the MagTool is set to 30 meter increments. These distance intervals are mutually exclusive from each other. This % overlap is used in combination with the predicted EEC at that off-site distance to determine anticipated species impacts, as described further below.
- Buffered overlap (used predominantly in Step 2) is calculated using the Euclidean distance of the aggregated use layers and includes the use sites and spray drift, out to the limits of the drift models, for the specific use application method. The full species range is used in this calculation, the area within and outside the lower 48.
- Spray drift overlap is calculated using the Euclidean distance of the aggregated use layers with the interval set to 30 meters and represents the overlap unique to the interval. The full species range is used in this calculation, the area within and outside the lower 48.

Aquatic MagTool

Aquatic Fish and Invertebrates

Species ranges for aquatic fish, invertebrates, and plants were determined based on HUC 12s which contain the waterbodies associated with the species. The percent overlap is determined for each HUC 12 in the species range with each of the non-ag and yearly ag use sites and is used to adjust the percent of a species population that may be exposed to EECs from that use, or as a means to adjust the EECs for medium and large flowing waterbodies. The 30 annual maximum daily or period (*e.g.*, 4-day, 21-day, or 60-day) average EECs for each Pesticide in Water Calculator (PWC) run for a use are used to simulate the range of exposure concentrations to which the species could be exposed. While the PWC runs are conducted at the larger 2-digit HUC level (HUC 2), HUC 12s are subsets of the HUC 2s and the HUC 2 EECs are intended to represent exposure within the HUC 12 species ranges. All of this information, coupled with the effects endpoints of interest, is used to estimate a distribution of exposure and effects to the species population.

Different methods are used for species depending on if they are in flowing or static waterbodies and if they are in single or multiple HUC 12s.

For static waterbodies and low-flow flowing waterbodies (Bins 2 and 5-7; described in Attachment 3-1 of BEs, https://www.epa.gov/endangered-species/biological-evaluation-chapters-chlorpyrifos-esa-assessment#attachments-3), pesticide loading is assumed to be from local uses (e.g. adjacent fields) and exposure, therefore, will be associated with specific uses within the HUC 12. For the medium and large-flow flowing waterbodies (Bins 3 and 4), pesticide exposure is associated with transport from all uses within an entire watershed (represented in this case the HUC 12). For the static and low-flow flowing waterbodies, the percent overlap was used, as it was in the terrestrial version of the tool, as a surrogate for percent of the species exposed to a use's EECs. For medium and high-flow flowing waterbodies, the EECs were adjusted using the percent overlap, much as a percent crop area adjustment factor would be used, and summed to develop an EEC to which the entire population in the HUC 12 would be exposed.

For a species range which is limited to a single HUC 12, the entire species population is exposed to EECs associated with that HUC 12. For a species range that spans multiple HUC 12s, it is uncertain how much of the species population is associated with each of the HUC 12s. The user can assume a uniform distribution of the species throughout the species range. In this case, the fraction of the area of a HUC 12 in the species range is used as a surrogate for the fraction of the population in the HUC 12. The user can alternatively assume a non-uniform distribution across the HUC 12s. The user may have information on the species' distribution within the range that can inform a species' distribution within their range, including: meta-populations, age cohorts, and other life history characteristics. In these cases, the user will need to specify the percent of the population associated with each HUC 12 in the species range.

Below is a more detailed description of the methodology used to estimate the probability distributions for mortality and sublethal effects for species assumed to have a uniform distribution across the HUC 12s.

For species in static waterbodies and low-flow flowing waterbodies (Bins 2 and 5-7) with a range limited to a single HUC 12:

1. An estimate of the pesticide use footprint within the single HUC 12 watershed corresponding to the species range is developed using the 6 annual summaries of general CDL use site classes and non-ag use sites.
2. The percent mortality is estimated using 30-year annual maximum daily or 4-day average EECs for the uses in the HUC 12. For sublethal endpoints, the 30-year annual maximum daily, 4-day, 21-day, or 60-day average EECs are used for the uses in the HUC 12 to estimate the percent of the population exposed to an EEC that may meet or exceed the sublethal endpoint (exposure periods should be selected that most accurately reflect the duration of study from which toxicity endpoint are derived). If an EEC meets or exceeds

the sublethal endpoint, the entire population exposed to that EEC is exposed to an EEC that meets or exceeds the sublethal endpoint. Otherwise, none of the population is exposed.

3. The percent mortalities and sublethal exceedances are adjusted using the 6 CDL percent use footprints. This results in 180 values (30-year annual maximum values x 6 different CDL percent use layers) for each use.
4. For each year/percent use combination, the percent mortalities and percent meeting or exceeding the sublethal effects are summed across the uses to estimate the effects to the entire population. This results in 180 values for the HUC 12, which is used to develop a probability distribution for the entire population.

For species in static waterbodies and low-flow flowing waterbodies (Bins 2 and 5-7) with a range larger than a single HUC 12, the same process, as discussed above, is used, except each HUC 12 is assigned a weight based on the acreage of the HUC 12 in relation to the entire range. The same steps as discussed above are applied along with:

1. The percent mortalities and percent meeting or exceeding the sublethal effects across uses for each HUC 12 is multiplied by the fraction of the population in the HUC 12 to estimate the effects to the subpopulation in the HUC 12. This results in 180 values for the HUC 12, which is used to develop a probability distribution for the subpopulation in the HUC 12.
2. To determine the population effects distribution across the entire range (all HUC 12s combined), for each year/percent use combination, the weighted percent mortalities and percent meeting or exceeding the sublethal effects are summed across uses for each of the HUC 12s above to estimate the effects to the entire population. This results in 180 values for the species range, which is used to develop a probability distribution for the species population.

For species in medium and high-flow flowing waterbodies (Bins 3 and 4) that have a range limited to a single HUC 12:

1. The individual use footprints within the single HUC 12 watershed corresponding to the species range is estimated using the 6 annual summaries of generalized CDL classes and the non-ag use site.
2. The 30-year annual maximum daily or 4-day average EECs are adjusted for the medium and high-flowing waterbodies (Bins 3 and 4) for each use in HUC 12 based on percent use area. For sublethal effects, the 30-year annual maximum daily, 4-day, 21-day, or 60-day average EECs for each use in the HUC 12 are adjusted based on the percent use area.
3. The adjusted EECs are aggregated.
4. Assuming the entire population in HUC 12 is exposed to the aggregated EEC, the distribution of percent mortality for the population using dose response curve and probability of meeting or exceeding a sublethal endpoint is determined using aggregated EECs in the HUC 12 for each year.

For species in medium and high-flow flowing waterbodies (Bins 3 and 4) that have a range larger than a single HUC 12, the same process, as discussed above, is used, except each HUC 12 is assigned a weight based on the acreage of the HUC 12 in relation to the entire range. The same steps as discussed above are applied along with:

1. The percent mortality is multiplied by the percent of the population in HUC 12. This is repeated for the probability of exceeding a sublethal endpoint.
2. The results from Step 2 are summed to determine the percent mortality/probability of exceeding sublethal effect for total population.

Results for exposures resulting from unmapped uses (i.e. Mosquito Control and Wide Area) were each calculated by separate runs of the MagTool. These uses are considered to have 100% overlaps with species ranges. Therefore, they would overlap with other uses and the MagTool could readily produce difficult to interpret results (e.g. >100% mortalities).

Spray Drift Effects – Incorporating Euclidan distance overlap with EECs to predict mortality

Aquatic

The Aquatic MagTool employs the same algorithm used in AgDRIFT to estimate aquatic EECs resulting from spray drift only. The tool estimates the drift across the waterbody width at 30-meter distances away from a treated field. The product of this average drift and the application rate, divided by the depth of the waterbody, results in a short-term average concentration in the waterbody due to spray drift. This concentration is then used to estimate the percent mortality that could potentially occur in a waterbody exposed to spray drift. Unlike the terrestrial tool, no application of percent overlap from the Euclidean distance is applied to the aquatic EECs.

Attachment 1. Redundancy in spatial overlap between CDL use layers

E. APPENDIX: RISK HYPOTHESES FOR CRITICAL HABITAT

All Salmonids

- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater spawning sites.
- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in freshwater rearing sites.
- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality, natural cover, and/or reductions in prey in freshwater migratory corridors.
- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in estuarine areas.
- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality and/or reductions in prey in nearshore marine areas.

Atlantic salmon

For Atlantic salmon, NMFS jurisdiction is limited to the marine environment only. However, specific areas of designated critical habitat were not identified within the marine environment (71 FR 69054). Therefore, NMFS did not assess impacts to designated critical habitat of Atlantic salmon in this Opinion; these impacts are addressed by FWS.

Sturgeon – Gulf

- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.
- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.

Sturgeon – Green

- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater habitats.
- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in freshwater habitats.
- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in estuarine habitats.
- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in estuarine habitats.
- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in coastal habitats.
- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in coastal habitats.

Eulachon

- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in freshwater and estuarine habitats.
- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in freshwater and estuarine habitats.
- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality in nearshore and offshore habitats.
- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in nearshore and offshore habitats.

Rockfish

- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.
- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.

Sawfish

- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey in shallow euryhaline habitats.

Steller Sea Lion

- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.

Hawaiian Monk Seal

- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey within 0-200 meters of depth.

Killer Whale

- Direct exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.
- Exposure to the stressors of the action outside of designated critical habitat is sufficient to in-directly reduce the conservation value via reductions in prey availability (Chinook salmon).
- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.

Black Abalone

- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality.
- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey.

Elkhorn Coral & Staghorn Coral

PBFs identifies are not anticipated to be effected by the action.

Johnson's Seagrass

- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality

Green Sea Turtle & Hawksbill Sea Turtle

- Exposure to the stressors of the action is sufficient to reduce conservation value via degradation of water quality

Leatherback Sea Turtle

- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey (jelly fish).

Loggerhead Sea Turtle

- Exposure to the stressors of the action is sufficient to reduce conservation value via reductions in prey (sargassm, copopods).

F. APPENDIX: R-PLOT GENERATION

To provide an aid in the Risk Characterization section, NMFS developed a plot (referred to as an 'R-plot') displaying the various sources of data (i.e. exposure, response, and use) available in EPA's Biological Evaluation (BE). The R-plots are generated using the R programming language:

R Core Team (2017). R: A language and environment for statistical computing. R Foundation for Statistical Computing, Vienna, Austria. URL https://www.R-project.org/.

This Appendix consists of several sections with information on the R-plot process:

- **R-plot Process Overview:** An overview of the R-plot process
- **Example R-Plot:** An example of an R-plot
- **Directory and Files:** A list of the directories and file needed by the R-plot process
- **R code lines to modify:** A description of inputs to change in the R code
- **Toxicity Data File:** An example of a toxicity data file used by the R code
- **HUC-12 List File:** An example of a HUC-12 list that may be used by the R code
- **Main R Code:** The primary R code file used to generate R-plots
- **Import R Code:** R code used to import data prior to running the main R code
- **Functions R Code:** R code defining several functions used by the other R code

R-plot Process Overview
The following is a brief overview of the R-plot process. The overview assumes an understanding of the data within the BE and Biological Opinion and some knowledge of the R programming environment.

The data displayed on the R-plots comes from three sources. For the R-plot process, these sources appear as various files that the R code relies on for generating the plots. A list of the files is provided in the **Directory and Files** section. A summary of the sources is detailed here:

1) Toxicity information for a species gathered from the available literature and presented in the BE. For sublethal endpoints, such as growth, this is typically a range of LOECs across the available studies. For endpoints such as mortality, this is can be a range of percent mortalities using an LC50 and slope chosen based on a species sensitivity distribution. For the R-plot process this information is provided by a tab-delimited text file generated by the user (an example is provided in **Toxicity Data File**).
2) Data on the species range and critical habitat (e.g. a list of HUC-12s), the uses of the pesticide (e.g. Vegetable and Ground Fruit), and their overlap (by HUC-12). This information is from the GIS analysis presented in the BE. For the R-plot

process, this information is provided by various files distributed by EPA with the BE and the MagTool. Files such as species_huc12.csv (in the bin directory of the MagTool) provide a list of HUC-12s by species. The various CDL files (e.g. CDL_L48_2010.csv in the bin directory) provide a list of uses and their overlaps for each of the HUC-12s.

3) Exposure estimates generated by EPA using the Pesticide Water Calculator (PWC). For each crop and use category (e.g. lettuce crop within the Vegetable and Ground Fruit use category) EPA generated thirty years of EECs for each HUC-2 and aquatic bin. The resulting data is provided with the BE and the MagTool. For the R-plot process, the thirty annual peak EECs for four different averaging periods are provided by files distributed with the MagTool (e.g. chlorpyrifos_eec.csv in the EECs directory).

The process of generating an R-plot typically starts with selecting a chemical and species. The selection of species determines which HUc-12s are extracted from the data files. The selection of chemical determines the relevant EECs and uses for the list of HUC-12s. The list of HUC-12s determines which HUC-2s are needed from the EEC data.

The plot only displays a single EEC range for a specific crop and use category (e.g. lettuce as a Vegetable and Ground Fruit use). If the list of HUC-12s spans multiple HUC-2s an adjustment can be made that computes a weighted average of the multiple HUC-2 EECs available. This adjustment is based on the proportion of the total area represented by each HUC-2. The more area of HUC-12s that belong to a HUC-2, the more that the EECs for that HUC-2 will contribute to the EECs displayed on the plot.

The R code compiles these sources of information into a single plot. An example of an R-plot is shown in **Example R-Plot**. The plot consists of five parts.

1) The upper portion displays the information present in the selected toxicity data file. This consists of multiple rows of endpoints each with a set of labeled markers. The meaning of each marker is up to the user (e.g. a LOEC, percent morality, etc.). The markers are positioned along the concentration axis below.
2) The center of the plot displays all the EEC data associated with the selected chemical, HUCs and relevant PWC scenarios. Each point represents the median peak annual EEC for one averaging period for a specific PWC scenario. For each crop (e.g. lettuce) of a use category (e.g. Vegetables and Ground Fruit) there will be a point for each averaging period and each aquatic bin. Error bars around the point indicate the 5% and 95%tile of the distribution of thirty years of data. The EEC data is positioned using the same concentration axis as the toxicity data to allow direct comparison of exposure and effects.
3) The left side of the plot (i.e. the left Y-axis labels) list the use categories associated with the species range (or list of HUC12s) in order of their area (largest area at the top). The area of each use category is denoted in the parentheses. Mosquito Control and Wide Area Use will be at the top due to their allowed use anywhere. The bin 3 and 4 estimates for the entire range (a 'watershed') account for the contribution of each use-specific EEC to the watershed based on the

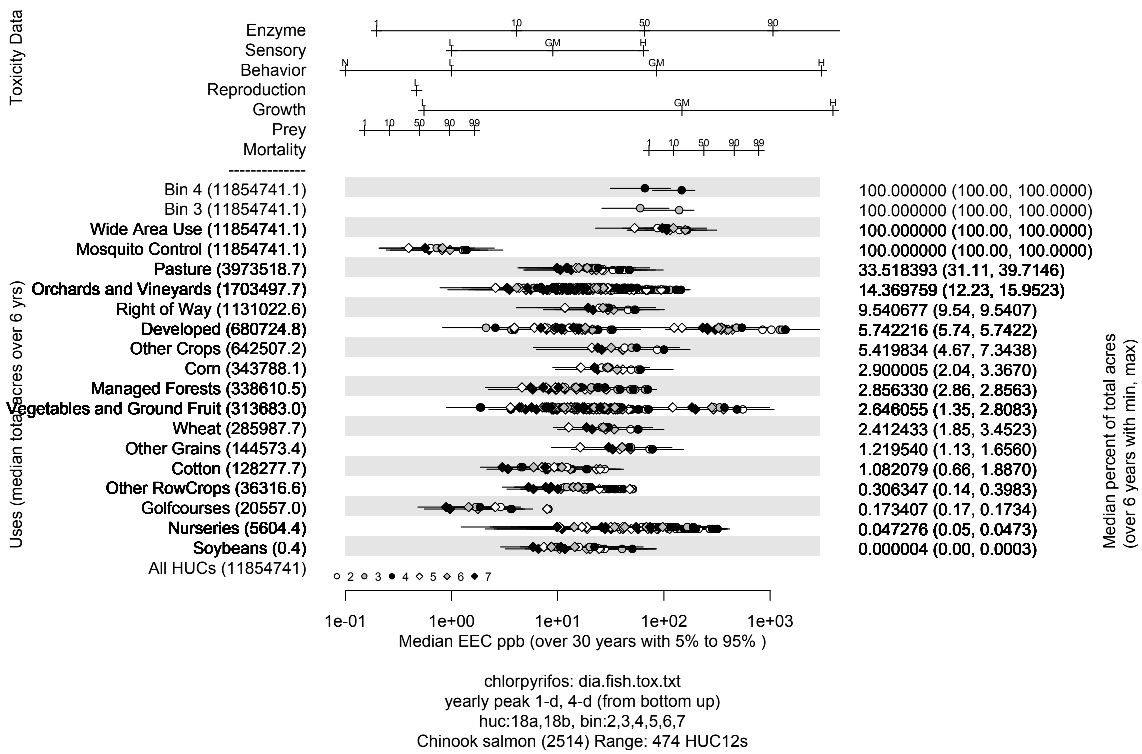
proportion of the range represented by the use.

4) The right side of the plot (i.e. the right Y-axis labels) shows the percent of the range represented by each use. For each use, six years of overlap data were provided and the median, minimum, and maximum percent overlaps are shown.
5) The bottom of the plot has four lines of text that identify the specific information presented in the R-plot. The first line shows the chemical and toxicity data file. The second line shows which averaging periods were plotted. The third line lists the HUC-2s and bins from which the EECs were selected. The fourth line shows some species and range info (e.g. number of HUC-12s).

Running the R code requires a collection of files and folders (see **Directory and Files**). In brief, the R-plot process begins with converting several files (see **Directory and Files**) into R objects using one of the R files (*AqEECsImportMagToolDataC.R).* This needs to be done once each time the source data changes. Generating an R-plot then involves editing several lines within the main R file (*AqEECsSummariesWithOverlapY.R*) to select the desired information (e.g. the chemical and species) and then running ('Source') the code. Details on these lines in the R code is provided in **R code lines to modify**. The resulting plot can then be saved as needed by the user. Generating a different R-plot entails editing a few lines as needed and repeating the process.

Example R-Plot

Example of a plot generated by the R code.



Directory and Files

List of files and directories associated with running the R-code. They all need to be in the same directory. There are three R files (identified in italics below), the code of which is provided later in this document.

File/folder	Comments
AqEECsSummariesWithOverlapY.R	Main R-code run to generate plot
AqEECsFunctionsB.R	Functions loaded by main file

R code lines to modify

Several specific lines of the R code define the information plotted. The values for the variables specified in these lines determine the resulting R-plot (e.g. the species and chemical). These lines are located at the beginning of the R code just after the following comment.

```
# select data to summarize ***********  USER selection section of inputs
```

Changing these values prior to running the R code is how different R-plots are generated.

An element from each of these lists is chosen in lines below.

```
chemlist<-c("chlorpyrifos","diazinon","malathion")
readoptions<-c("Species range","Read from file","Choose HUC2s")
```

Changing the index of chemlist determines which chemical is summarized (e.g. which EEC data is used).

```
chemtext<-chemlist[1] # *************** select chemical from chemlist above e.g. 1 for cpy, 2 for dia, 3 for mal
```

The value of toxfilename specifies the file containing the toxicity data used to generate the toxicity display at the top of the R-plot. The file needs to exist in the same directory as the R code file. An example of a file is below.

```
toxfilename<-"dia.fish.tox.txt" # file with info for toxicity data section of the plot
```

The index of readoptions determines which HUCs are used to generate the uses and overlaps shown on the R-plot. Species range uses the HUC12s associated with the species. Read from file uses a list of HUC12s specified in a file the user is asked to select. Choose HUC2s uses the HUC2s specified in a variable below.

```
readhucs<-readoptions[1] # ****************** how to get HUC12 and HUC2 lists, from readoptions list e.g. 1 for "Species range"
```

The value of speciesID determines which species is summarized (e.g. which HUC12s are used).

```
speciesID<-2514 # ************* Select species Entity ID
```

The value of plotHabitat determines whether the plot is based on HUCs in the species range (True) or the designated critical habitat (False).

```
plotHabitat<-FALSE # set to true to plot critical habitat rather than species range
```

Use to force the plot to be based on selected HUC2s (False) rather than HUC12s (True).

```
useHUC12s<-True # ****************** use HUC12 info otherwise rely on HUC2 and don't plot overlap
```

Lines used to determine which aquatic bins are summarized in the plot. Changing useSpeciesBins to False will plot only the bins specified by bintext and not all the bins associated with a species. The bin 3 and 4 EECs associated with individual uses can be omitted by changing the lines to True. The aggregated bin 3 and bin 4 EECs across the collection of HUC12s (the 'watershed') are plotted separately.

```
useSpeciesBins<-True # **************** plot all the bins
assigned to a species or specific bins
OmitBin3<-False  # **************** don't plot bin 3 values for
individual uses
OmitBin4<-False  # **************** don't plot bin 4 values for
individual uses
bintext<-c("2","6","7") # *************** bins to plot if not
based on species
```

The HUC-2s specified in huctext are used to determine the EEC data summarized if the HUC-2s aren't specified by the species data.

```
huctext<-c("18a") # *************** list of HUC2s for EEC data if
not specified by the species HUC12 list
```

The values in avgper determine which EEC averaging periods are plotted. Any combination of 1, 2, 3, and 4 can be specified.

```
avgper<-c(1,2) # ************** EEC averaging periods to plot, 1-
4 correspond to 1-d, 4-d, 21-d, 60-d
```

The value of multiHUC2adj determines how to adjust for multiple HUC2 regions in the species range. Set to False will average the HUC-2 EECs without respect to area, while True will account for the proportion of the total range represented by each HUC-2 as described above. This will involve more computation time.

```
multiHUC2adj<-TRUE # if multiple HUC2s adjust EECs based on
proportion of total area
```

Toxicity Data File

Example of toxicity data file used to generate toxicity data at the top of the plot. Needs to be a tab-delimited file with two columns for each endpoint. Endpoints are plotted in reverse order (i.e. first column pair appears at the bottom of the toxicity data). The first row has the name of the endpoint in the first column that will be used on the plot with the second column being ignored. The remaining rows contain data that will be plotted. The first column has the concentration and the second column has the label for the point.

Mortality	M.labels	Prey	P.labels	Growth	G.labels	Reproduction	R.labels	Behavior	B.labels	Sensory	S.labels	Enzyme	E.labels
72.3	1	0.15	1	0.55	L	0.47	L	0.1	N	1	L	0.196	1
123.5	10	0.26	10	148	GM			1	L	9	GM	4.086	10
237.9	50	0.50	50	3915	H			85	GM	64	H	65.95	50
458.3	90	0.96	90					3043	H			1064.43	90
782.3	99	1.64	99									22148.04	99

HUC12 List File

Example of a HUC12 list. Needs to be a tab-delimited file. The first row has the name of the region. This is used by the R code to present a list from which the user selects the desired HUC12s to plot. The remaining rows are the HUC12s to use to generate the plot.

Main R Code

The primary R code file. Any changes to the code should be made (e.g. modify the USER selection lines), the code should then be saved, and then the code should be "Sourced". This allows the first line of the code to determine the folder the code is in and therefore how to find the support folders needed.

Import R Code

R code to import various data files and generate R objects for use in *AqEECsSummariesWithOverlapY.R.* Needs to be run at least once to generate R objects. Also, needs to be run anytime that the data used to generate plots has been updated (e.g. EPA releases new data). Needs to be saved and then 'sourced' in order for the first line to determine where the file is located and find the folder to save the R objects.

AqEECsImportMagToolDataC.R

```
# establish directories
wd<-dirname(sys.frame(1)$ofile) # get dir of sourced R script and other
dir
mdir<-"MagTool Data" # dir name with MagTool data within dir with script
rdir<-"R Objects" # dir name for R objects within dir of R script

# _____________ EECs.df
# import EEC files into a single dataframe
# set file names for EEC files
